1.0 Function Group AisHandler

1.1 Supporting Data Types

1.1.1 AisHandlerType

Synopsis

```
#include <AisHandler.h>
typedef void (*AisHandlerType)(int fd_or_sig)
```

Description

This data type represents a function pointer that points to an event handler that is called when
a noteworthy event takes place. Noteworthy events are a file descriptor managed by the instru-
mentation system receives input, clears space for output, or a signal managed by the instru-
mentation system has been raised.
1.2 Ais_add_fd

Synopsis

#include <AisHandler.h>
AisStatus Ais_add_fd(int fd, AisHandlerType handler)

Parameters

fd file descriptor
handler function handler for this socket

Description

Add a file descriptor and input handler to the list of file descriptors managed by the instrumentation system. When input is received by the file descriptor, the handler is called to handle the input. The handler is expected to accept the file descriptor as its input parameter.

Return value

ASC_success request successful
ASC_operation_failed request failed

See Also

Ais_add_signal, Ais_next_fd, Ais_remove_fd, Ais_remove_signal
1.3 Ais_add_signal

Synopsis

```
#include <AisHandler.h>
AisStatus Ais_add_signal(int signal, AisHandlerType handler)
```

Parameters

- `signal`: signal to be caught
- `handler`: function handler for this signal

Description

Add a signal and signal handler to the list of signals managed by the instrumentation system. When a signal is received, the handler is called to handle the signal. The handler is expected to accept the signal as its input parameter. The instrumentation system ensures that signals registered with the instrumentation system will not interfere with its system calls. Signal handlers executed by the instrumentation system are executed on the normal application stack. In the event that multiple signals occur while a signal handler is being executed, the executing handler is completed before the next handler is begun. This provides a measure of safety for operations that are normally considered unsafe for signal handlers, such as memory allocation.

Return value

- `ASC_success`: request successful
- `ASC_duplicate_signal`: attempt to add a handler for a signal that already has a handler
- `ASC_invalid_operand`: attempt to add a handler for a signal which does not exist
- `ASC_operation_failed`: system call to add a signal failed

See Also

- `Ais_add_fd`, `Ais_next_fd`, `Ais_remove_fd`, `Ais_remove_signal`
1.4 Ais_next_fd

Synopsis

```c
#include <AisHandler.h>

void Ais_next_fd(int &fd_or_sig, AisHandlerType &handler)
```

Parameters

- **fd_or_sig**: file descriptor or signal number
- **handler**: file descriptor or signal handler function

Description

Return the file descriptor or signal number and associated handler of the next event to occur.

See Also

- Ais_add_fd
- Ais_add_signal
- Ais_remove_fd
- Ais_remove_signal
1.5 Ais_remove_fd

**Synopsis**

```
#include <AisHandler.h>
AisStatus Ais_remove_fd(int fd)
```

**Parameters**

- **fd** file descriptor

**Description**

Remove a file descriptor from the list of descriptors the instrumentation system manages. The file descriptor is unaffected by this operation, that is, it is neither closed nor flushed.

**Return value**

- **ASC_success** request successful
- **ASC_operation_failed** request failed

**See Also**

Ais_add_fd, Ais_add_signal, Ais_remove_fd, Ais_remove_signal
1.6 Ais_query_signal

**Synopsis**

```c
#include <AisHandler.h>
AisHandlerType Ais_query_signal(int signal)
```

**Parameters**

- `signal` signal for which handling is to be removed

**Description**

This function returns a pointer to the signal handler function for the specified signal, or 0 if there is none.

**Return value**

A pointer to the signal handler function for the specified signal if there is one. Otherwise 0 if there is no handler or the signal parameter does not represent a valid signal.

**See Also**

- Ais_add_fd, Ais_add_signal, Ais_next_fd, Ais_remove_fd
### 1.7 Ais_remove_signal

**Synopsis**

```c
#include <AisHandler.h>
AisStatus Ais_remove_signal(int signal)
```

**Parameters**

- `signal` : signal for which handling is to be removed

**Description**

Remove a signal and signal handler from the list of signals the instrumentation system manages. A previous handler is *not* restored for this signal.

**Return value**

- ASC_success : signal handler was successfully removed, or there was no handler to be removed
- ASC_invalid_operand : attempt to remove a handler for a signal that does not exist
- ASC_operation_failed : system call to delete a signal failed

**See Also**

- Ais_add_fd, Ais_add_signal, Ais_next_fd, Ais_remove_fd
2.0 class AisStatus

2.1 Supporting Data Types

2.1.1 AisStatusCode

Synopsis

```c
#include <AisStatus.h>
enum AisStatusCode {
    ASC_success, // normal status
    ASC_failure, // undefined error condition
    ASC_insufficient_memory, // failed to allocate memory
    ASC_invalid_constructor, //
    ASC_invalid_expression, // ill formed probe expression
    ASC_invalid_index, //
    ASC_invalid_internal_tree, //
    ASC_invalid_operand, //
    ASC_invalid_operator, //
    ASC_invalid_value_ref, //
    ASC_operation_failed, //
    ASC_duplicate_signal, //
    ASC_signal_not_found, //
    ASC_LAST_STATUS_VALUE
};
```

Description
### 2.1.2 AisSeverityCode

**Synopsis**

```c
#include <AisStatus.h>
enum AisSeverityCode {
    ASC_information,       //
    ASC_attention,        //
    ASC_error,            //
    ASC_severe,           //
    ASC_LAST_SEVERITY_VALUE
}
```

**Description**
2.2 Constructors

Synopsis

#include <AisStatus.h>
AisStatus(
    AisStatusCode status = ASC_success,
    AisSeverity severity = ASC_information)
AisStatus(const AisStatus &copy)

Parameters

status            Valid values are 0 code < ASC_LAST_STATUS_VALUE
severity          Valid values are 0 code < ASC_LAST_SEVERITY_VALUE

Description

Class constructor. This constructor initializes the object to reflect the specific status and severity codes.

Exceptions

An exception of type AisStatus with value ASC_invalid_constructor and severity ASC_attention is raised if the code is not a valid AisStatusCode value or the severity is not a valid AisSeverityCode.
2.3 add_data

Synopsis

```c
#include <AisStatus.h>

void add_data(const char *data) const
```

Parameters

- `data` a pointer to a character string representation of the data.

Description

This function adds one data value to the list of data associated with this condition.

See Also

- `data_count`, `data_value`
2.4 data_count

Synopsis

#include <AisStatus.h>

int data_count(void) const

Description

This function returns the number of data values associated with this condition.

Return value

The count of data values reflected in the object.
2.5 data_value

Synopsis

```
#include <AisStatus.h>
const char *data_value(int i) const
```

Parameters

i
index value

Description

This function returns a character string representation of the $i$th data value.

Return value

A pointer to the $i$th data string if the index is valid, that is, $0 \leq i < \text{data_count()}$.

A null pointer if the index is not valid.
2.6 operator =

Synopsis

```
#include <AisStatus.h>

AisStatus &operator = (const AisStatus &copy) const
```

Parameters

- `copy` object to be copied in the assignment

Description

This function copies the right hand side of the assignment expression over the left hand side.

Return value

A reference to the copied object, which is the left hand side of the assignment or the invoking object, depending upon the perspective.
2.7 operator AisStatusCode

Synopsis

```
#include <AisStatus.h>
operator AisStatusCode(void) const
```

Description

Cast function. This function returns the status code reflected in the object.

Return value

The status code in the object, of data type AisStatusCode.
2.8 operator int

Synopsis

```c
#include <AisStatus.h>
operator int(void) const
```

Description

Cast function. This function returns the integer equivalent of the status code reflected in the object. A status value of zero reflects a “normal” status.

Return value

Integer equivalent of the status value AisStatusCode, and zero reflects “normal” status.
2.9 severity

Synopsis

```c
#include <AisStatus.h>
AisSeverityCode severity(void) const
```

Description

Explicit severity function. This function returns the severity code reflected in the object.

Return value

The severity code in the object, of data type `AisSeverityCode`. 
2.10 status

Synopsis

```
#include <AisStatus.h>
AisStatusCode status(void) const
```

Description

Explicit status function. This function returns the status code reflected in the object.

Return value

The status code in the object, of data type AisStatusCode.
2.11 status_name

Synopsis

```c
#include <AisStatus.h>

const char *status_name(void) const
```

Description

This function returns the name of the status code reflected in the object. The name is in American English, and the string is stored in a constant array within the function. This function is intended only for limited diagnostic use during tool development.

Return value

The name of the status code in the object, of data type `char *`. 
3.0 class Application

3.1 Constructors

Synopsis

    #include <Application.h>
    Application(void)

Description

Default constructor.

Note: What functions in this base class should be virtual? All of them? None?

Exceptions

Exceptions that could be raised as a result of calling this function are unknown at this time.

AisStatus ???
3.2 activate_probe

Synopsis

```c
#include <Application.h>
AisStatus activate_probe(
    short count,
    ProbeHandle *phandle,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- **count**: number of probe expressions in the list to be activated
- **phandle**: array of probe handles, one for each probe expression to be activated
- **ack_cb_fp**: acknowledgement callback function to be invoked each time all probe expressions in the array have been activated (or activation fails) within a process
- **ack_cb_tag**: tag to be used with the acknowledgement callback function

Description

This function activates a list of probes that have been installed within an application. The activation is atomic in the sense that all probes are activated or all probes fail to be activated for any given process within the application. Some processes within the application may successfully activate the probes while other processes fail, but within a process either all probes are successfully activated or none are activated. Probes are activated independently across processes, that is, there is no synchronization to ensure that the probes are activated in all processes at the same time.

**Phandle** is an input array generated by an install_probe or binstall_probe call. It is supplied by the caller and must contain at least **count** elements. The \(i^{th}\) element of the array is a handle, or identifier, that identifies the \(i^{th}\) probe expression.

To activate a set of probes the processes must have been previously connected, and the probes must have been previously installed in those processes.

Note that activate_probe returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until the probes have been activated or failed to be activated in all processes within the application. The acknowledgement callback function receives notification of the success or failure of the activation. The callback is activated once for each process within the application.
Return value

The return value indicates whether the requests for activation were successfully submitted, but indicates nothing about whether the requests themselves were successfully executed.

ASC_success all activations were successfully submitted
ASC_???

Callback Data

The callback function is invoked once for each process for which a probe activation is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

ASC_success probes were successfully activated on this process
ASC_operation_failed attempt to activate these probes in this process failed

See Also

bactivate_probe, bconnect, bdisconnect, bprobe_deactivate, bprobe_install, class Process, connect, disconnect, GCBFuncType, probe_deactivate, probe_install.
3.3 add_phase

Synopsis

```c
#include <Application.h>
AisStatus add_phase(
    Phase ps,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- **ps**: data structure local to the client containing the characteristics of the phase to be created
- **ack_cb_fp**: acknowledgement callback function to be invoked each time the phase has been created within a process
- **ack_cb_tag**: tag to be used with the acknowledgement callback function

Description

This function adds a new phase structure to each connected process within the application. A process *must* be connected in order to add a new phase.

Note that add_phase returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until the phase has been installed or failed to be installed in all processes within the application. The acknowledgement callback function receives notification of the success or failure of the installation. The callback is activated once for each process within the application.

Return value

The return value indicates whether the requests for phase addition were successfully submitted, but indicates nothing about whether the requests themselves were successfully executed.

- **ASC_success**: all phase additions were successfully submitted
- **ASC_operation_failed**: attempt to add a phase to some process failed, perhaps because the process is not connected

Callback Data

The callback function is invoked once for each process for which a phase addition is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

- **ASC_success**: phase was successfully added to this process
ASC_operation_failed  attempt to add a phase to this process failed, perhaps because the phase is already added to the process

See Also

badd_phase, bconnect, bdisconnect, class GenCallBack, class ProbeMod, class Process, connect, disconnect, GCBFuncType, GCBTagType, Process::malloc, Process::free.
3.4 add_process

Synopsis

#include <Application.h>

AisStatus add_process(const Process &p)

Parameters

p process to be added to the application

Description

This function adds a process to the set of processes managed by the application. This operation acts locally within the end-user tool. It does not attempt to connect to the process. The process state (e.g. connected or attached) is not required to match the state of all other processes within the application.

The index of a process is not guaranteed to remain invariant when new processes are added to or removed from an application. The index does remain invariant otherwise.

Return value

The return value indicates whether the process addition was successful.

ASC_success process was successfully added

ASC_operation_failed attempt to add this process to this application failed

See Also

connect, bconnect, bdisconnect, disconnect, remove_process.
3.5 attach

Synopsis

```c
#include <Application.h>
AisStatus attach(GCBFuncType fp, GCBTagType tag)
```

Parameters

- **fp**: callback function to be invoked with each successful or failed attachment to a process listed within the application.
- **tag**: callback tag to be used as a parameter to the callback each time the callback function is invoked.

Description

Attach to all processes within an application. When multiple tools are connected to a process or application, only one tool can be attached at a time. Attaching to a process or application allows the tool to control the execution directly, setting break points, starting, suspending and resuming execution, etc. Processes must be first connected before they can be attached.

Note that `attach` returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until all processes within the application have attached or failed to attach. The acknowledgement callback function receives notification of the success or failure of the activation. The callback is activated once for each process within the application.

Return value

The return value for `attach` indicates whether the requests were successfully submitted, but indicates nothing about whether the requests themselves were successfully executed.

- **ASC_success**: all requests to attach were successfully submitted
- **ASC_operation_failed**: attempt to request attachment to some process failed, perhaps because the process is not connected

Callback Data

The callback function is invoked once for each process for which an attach is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- **ASC_success**: process was successfully attached
- **ASC_operation_failed**: attempt to attach to this process failed

See Also

- `connect`, `bconnect`, `bdisconnect`, `detach`, `disconnect`. 
3.6 bactivate_probe

Synopsis

```c
#include <Application.h>

AisStatus bactivate_probe(short count, ProbeHandle *phandle)
```

Parameters

- `count`: number of probe expressions in the list to be activated
- `phandle`: array of probe handles, one for each probe expression to be activated

Description

This function activates a list of probes that have been installed within an application. The activation is atomic in the sense that all probes are activated or all probes fail to be activated for any given process within the application. Some processes within the application may successfully activate the probes while other processes fail, but within a process either all probes are successfully activated or none are activated. Probes are activated independently across processes, that is, there is no synchronization to ensure that the probes are activated in all processes at the same time.

`phandle` is an input array generated by an `install_probe` or `binstall_probe` call. It is supplied by the caller and must contain at least `count` elements. The `i`th element of the array is a handle, or identifier, that identifies the `i`th probe expression.

To activate a set of probes the processes must have been previously connected, and the probes must have been previously installed in those processes.

Note that the function submits the requests to activate the probes and waits until the requests have completed. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value indicates whether all of the requests for activation were successfully executed. The return value reflects the highest severity encountered across all processes.

- `ASC_success`: all activations were successfully completed
- `ASC_operation_failed`: one or more of the activations failed

See Also

- `activate_probe`, `bconnect`, `bdisconnect`, `bprobe_deactivate`, `bprobe_install`, `connect`, `disconnect`, `probe_deactivate`, `probe_install`. 
3.7 badd_phase

Synopsis

```c
#include <Application.h>
AisStatus badd_phase(Phase ps)
```

Parameters

ps data structure local to the client containing the characteristics of the
phase to be created

Description

This function adds a new phase structure to each connected process within the application. A process must be connected in order to add a new phase.

Note that the function submits the requests to add the phase and waits until the requests have completed. The return value indicates whether all of the requests were successfully executed. The function Application::status(int index) may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value indicates whether requests to all processes for phase addition were successfully executed. The return value reflects the highest severity encountered across all processes.

ASC_success phase was successfully added to all processes
ASC_operation_failed one or more of the phase additions failed

See Also

add_phase, bconnect, bdisconnect, class ProbeMod, connect, disconnect, Process::malloc, Process::free.
3.8 battach

Synopsis

```c
#include <Application.h>
AisStatus battach(void)
```

Description

Attach to all processes within an application. When multiple tools are connected to a process or application, only one tool can be attached at a time. Attaching to a process or application allows the tool to control the execution directly, setting break points, starting, suspending and resuming execution, etc. A process must first be connected before it can be attached.

Note that `battach` does not return control to the caller until all attachments have either succeeded or failed. The return value indicates whether all succeeded or some succeeded and some failed. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for `battach` indicates whether the individual attachments themselves were successfully established. The return value reflects the highest severity encountered across all processes.

- `ASC_success` all processes were successfully attached as expected.
- `ASC_operation_failed` one or more of the processes failed to attach

See Also
### 3.9 bconnect

**Synopsis**

```c
#include <Application.h>
AisStatus bconnect(void)
```

**Description**

Connect to all processes within an application. Connection to a process establishes a communication channel to the CPU where the process resides and creates the environment within that process that allows the client to insert and remove instrumentation, alter its control flow, *etc*. Note that `bconnect` does not return control to the caller until all connections have either succeeded or failed. The return value indicates whether all connections succeeded or some succeeded and some failed. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

**Return value**

The return value for `bconnect` indicates whether the connections themselves were successfully established. The return value reflects the highest severity encountered across all processes.

- `ASC_success`: all connections were successfully established as expected.
- `ASC_operation_failed`: one or more of the connections failed to be established.

**See Also**
3.10 bcreate

Synopsis

```c
#include <Application.h>
AisStatus bcreate(
    const char *host,
    const char *path,
    char *const args[],
    char *const envp[])
```

Parameters

- **host**: host name or IP address of the host machine where the application is to be created
- **path**: complete path to the executable program, including file name and relative or absolute directory, when appropriate
- **args**: null terminated array of arguments to be provided to the executable
- **envp**: null terminated array of environment variables to be provided to the executable

Description

This function is currently being defined. It creates an application in a “stopped” state. Note that `bcreate` does not return control to the caller until the new application has been created or failed to be created. The return value indicates whether the operation succeeded or failed.

Return value

The return value for `bcreate` indicates whether the application was successfully created. The return value reflects the highest severity encountered across all processes.

- **ASC_success**: application was successfully created, as expected
- **ASC_operation_failed**: application failed to be created

See Also

- `bdestroy`, `bstart`, `create`, `destroy`, `start`
3.11 bdeactivate_probe

Synopsis

```cpp
#include <Application.h>
AisStatus bdeactivate_probe(short count, ProbeHandle *phandle)
```

Parameters

- **count**: number of probes to be deactivated
- **phandle**: array of probe handles, representing the probes, to be deactivated

Description

This function accepts an array of probe handles as an input parameter. Each probe handle in the array represents a probe that has been installed in the application. The client sends a request to each of the processes within the application to deactivate the list of probes represented by the array. Probes are deactivated atomically for each process in the sense that the process is temporarily stopped, all probes on the list are deactivated, then the process is restarted. None of the probes in the array are left active.

*Phandle is an input array generated by an install_probe or binstall_probe call. It is supplied by the caller and must contain at least count elements. The i\(^{th}\) element of the array is a handle, or identifier, that identifies the i\(^{th}\) probe expression.*

Note that bdeactivate_probe does not return control to the caller until all probes in the array have been deactivated on all processes in the application. The return value indicates whether all connections succeeded or some succeeded and some failed. The function Application::status(int index) may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for bdeactivate_probe indicates whether the deactivations were successfully completed. The return value reflects the highest severity encountered across all processes.

- **ASC_success**: all probe deactivations completed as expected
- **ASC_operation_failed**: one or more of the probe deactivations failed

See Also
3.12 bdestroy

Synopsis

```
#include <Application.h>
AisStatus bdestroy(void)
```

Description

This function destroys or terminates all processes within the application. Note that `bdestroy` does not return control to the caller until all processes within the application have been destroyed. The return value indicates whether all terminations succeeded or some succeeded and some failed. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for `bdestroy` indicates whether the terminations were successfully completed. The return value reflects the highest severity encountered across all processes.

- `ASC_success`         all terminations were successfully completed, as expected
- `ASC_operation_failed` one or more of the terminations failed

See Also
3.13 bdetach

**Synopsis**

```c
#include <Application.h>
AisStatus bdetach(void)
```

**Description**

This function detaches all processes in the application. Process control flow, such as stepping and setting break points, can only be done while a process is in an attached state. Detaching a process removes the level of process control available to the client or tool when the process is attached, but retains the process connection so probe installation, activation, removal, etc. can still take place.

Note that `bdetach` does not return control to the caller until all processes within the application have been detached. The return value indicates whether all processes successfully detached or some succeeded and some failed. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

**Return value**

The return value for `bdetach` indicates whether all processes were successfully detached. The return value reflects the highest severity encountered across all processes.

- **ASC_success**
  - all processes were successfully detached, as expected
- **ASC_operation_failed**
  - one or more processes failed to detach

**See Also**

- `attach`, `battach`, `detach`
3.14 bdisconnect

Synopsis

```c
#include <Application.h>
AisStatus bdisconnect(void)
```

Description

Disconnect from all processes within an application. Disconnecting from an application process removes the application environment created by a connection. All instrumentation and data are removed from the application process.

Note that `bdisconnect` does not return control to the caller until all processes within the application have either succeeded or failed in disconnecting. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for `bdisconnect` indicates whether the connections were successfully terminated. The return value reflects the highest severity encountered across all processes.

- `ASC_success` all connections were successfully terminated as expected
- `ASC_operation_failed` one or more of the connections failed to terminate

See Also
3.15 bexecute

Synopsis

```c
#include <Application.h>
AisStatus bexecute(ProbeExp pexp)
```

Parameters

- **pexp**: probe expression to be executed in the application process

Description

This function executes a probe expression in each process within an application. The expression is executed once in each process, then removed. The application process is interrupted, the expression is executed, then the process resumes execution as before the interruption.

Note that `bexecute` does not return control to the caller until the probe expression has either succeeded or failed to execute within all processes in an application. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for `execute` indicates whether the execution succeeded or failed.

- **ASC_success**: probe expression was successfully executed
- **ASC_operation_failed**: attempt to execute the probe expression failed

See Also

- execute
3.16 bfree

Synopsis

```c
#include <Application.h>
AisStatus bfree(ProbeExp pexp)
```

Parameters

- `pexp` dynamically allocated block of probe memory

Description

This function deallocates a block of dynamically allocated probe memory for every process in the application. The probe expression must contain only a single reference to a block of data allocated by the `malloc` or `bmalloc` functions.

Note that `bfree` does not return control to the caller until all processes within the application have either succeeded or failed in deallocating the block of memory. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for `bfree` indicates whether all requests for deallocation were successfully executed. The return value reflects the highest severity encountered across all processes.

See Also
3.17 binstall_probe

Synopsis

#include <Application.h>
AisStatus binstall_probe(
    short count,
    ProbeExp *probe_exp,
    InstPoint *point,
    GCBFuncType *data_cb_fp,
    GCBTagType *data_cb_tag,
    ProbeHandle *phandle)

Parameters

count number of probe expressions to be installed
probe_exp probe expressions to be installed
point instrumentation points where the probe expressions are to be installed
data_cb_fp callback functions to process data received from the probe expression
data_cb_tag tags to be used as an argument to the data callback when it is invoked
phandle probe handles that represent the installed probe expressions

Description

This function installs probe expressions as instrumentation at specific locations within each process in the application. Probe expressions are installed atomically, in the sense that within each process either all probe expressions in the request are installed into the process, or none of the expressions are installed. There is no synchronization across processes to assure that all processes install all probes. The return value indicates whether all probes were installed, or whether one or more processes were unable to install the expressions as requested.

Data_cb_fp is an input array supplied by the caller that must contain at least count elements. The ith element of the array is a pointer to a callback function that is invoked each time the ith probe in phandle sends data via the AisSendMsg function. Data_cb_tag is a similar array that contains the callback tag used when callbacks in data_cb_fp are invoked. The ith callback tag is used with the ith callback.

Phandle is an output array supplied by the caller that must contain at least count elements. The ith element of the array is a handle, or identifier, to be used in subsequent references to the ith probe expression. For example, it is needed when the client activates, deactivates or removes a probe expression from an application or process. Phandle does not contain valid information if the installation fails.
Note that `binstall_probe` does not return control to the caller until all probe expressions have been installed or failed to install within all processes within the application. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

**Return value**

The return value for `binstall_probe` indicates whether the probe installations were successful. The return value reflects the highest severity encountered across all processes.

- **ASC_success** all probes were successfully installed, as expected
- **ASC_operation_failed** one or more of the probes could not be installed as requested, so none of the probes were installed

**Callback Data**

The callback function is invoked once for each message sent from the probe. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback tag is given in the `data_cb_tag` array. The callback message is the data send by the probe using the `Ais_send()` function call.

**See Also**

- `AisSendMsg`, `install_probe`, ...
3.18 bload_module

Synopsis

#include <Application.h>
AisStatus bload_module(ProbeModule* module)

Parameters

Description

This function is currently being designed. The intent is to provide some means by which
instrumentation functions and probe classes might be loaded into an application for use by one
or more probe expressions.

Note that bload_module does not return control to the caller until the probe module has
been installed or failed to install in all processes within the application. The function Application::status(int index) may be queried to determine whether the operation suc-
ceeded or failed on any given process.

Return value

The return value for bload_module indicates whether the probe module installations were
successful. The return value reflects the highest severity encountered across all processes.

ASC_success module was successfully installed on all processes
ASC_operation_failed module could not be installed as requested on one or more
processes

See Also

bunload_module, load_module, unload_module
3.19 bmalloc

Synopsis

```c
#include <Application.h>

ProbeExp bmalloc(ProbeType pt, void *init_val, AisStatus &stat)
```

```c
ProbeExp bmalloc(
    ProbeType pt,
    void *init_val,
    Phase ps,
    AisStatus &stat)
```

Parameters

- `pt`: data type of the allocated data
- `init_val`: pointer to the initial value of the allocated data, or 0 if no initial value is desired
- `ps`: phase that will contain the allocated data
- `stat`: output value indicating the completion status of the function

Description

This function allocates a block of probe data in each process in the application. It returns a single probe expression that may be used to reference the allocated data. The data may be referenced in a probe expression that may be installed in any or all of the application processes where the data is allocated. The initial value of the data is as specified, or zero if not specified.

Note that `bmalloc` does not return control to the caller until it has either succeeded or failed on all of the processes within the application. If the allocation succeeds it returns a valid probe expression data reference and `stat` is given the value `ASC_success`. If the allocation fails on some process then `stat` is given the value `ASC_operation_failed` and any probe that references the returned value of `bmalloc` will fail to install on that process.

The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

A probe expression that may be used as a valid reference to the data on any process in which the data has been successfully allocated.

See Also

`bfree, free, malloc, status`
3.20 bremove_phase

Synopsis

```
#include <Application.h>
AisStatus bremove_phase(Phase ps)
```

Parameters

- `ps` phase description to be removed from the application

Description

This function removes a phase from the application. Data and functions associated with the phase are unaffected by removing the phase.

Note that `bremove_phase` does not return control to the caller until the phase has been removed or failed to be removed from all processes within the application. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for `bremove_phase` indicates whether the phase was successfully removed from all processes. The return value reflects the highest severity encountered across all processes.

- `ASC_success` all phases were successfully removed, as expected
- `ASC_operation_failed` phase could not be removed from one or more processes

See Also

- `add_phase`, `badd_phase`, `class Phase`, `remove_phase`
3.21 bremove_probe

Synopsis

```c
#include <Application.h>
AisStatus bremove_probe(short count, ProbeHandle *phandle)
```

Parameters

- **count**: number of probe handles in the accompanying array
- **phandle**: array of probe handles representing probe expressions to be removed

Description

This function deletes or removes probe expressions that have been installed in an application. If all probe expressions are installed and deactivated, the probe expressions are removed and a “normal” return status results. If one or more of the probe expressions are currently active, the expressions are deactivated and removed, and the return status indicates there were active probes at the time of their removal. If one or more of the probes do not exist, all existing probes are removed and the return status indicates an appropriate warning. If one or more of the probe expressions exists but cannot be removed, an error results and as many probes as can be are removed. If one or more processes are not connected, probe removal takes place within those that are connected, and a warning is issued.

`Phandle` is an input array generated by an `install_probe` or `binstall_probe` call. It is supplied by the caller and must contain at least `count` elements. The `i`th element of the array is a handle, or identifier, that identifies the `i`th probe expression.

Probe expression removal is atomic in the sense that all probe expressions are removed from a given process or none are. When probes are removed from a process the process is temporarily stopped, all indicated probes are removed, and the process is resumed. Probe expressions are removed in a process by process basis. There is no synchronization between processes to guarantee that all expressions are removed from all processes. One process may succeed while another one fails.

Note that `bremove_probe` does not return control to the caller until the probes have been removed or failed to be removed from all processes within the application. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for `bremove_probe` indicates whether all probes in the list were successfully removed from all processes. The return value reflects the highest severity encountered across all processes.

- **ASC_success**: all probes were successfully removed, as expected
- **ASC_operation_failed**: none of the probes were removed
See Also

bactivate_probe, bdeactivate_probe, binstall_probe,
activate_probe, deactivate_probe, install_probe, remove_probe
3.22 bresume

Synopsis

```c
#include <Application.h>
AisStatus bresume(void)
```

Description

This function resumes execution of an application that has been temporarily suspended by a `suspend` or `bsuspend` function. Execution resumption occurs on a process by process basis. A process must be connected, attached and stopped for it to be resumed. A process that is not connected or not attached will result in a warning return code. A process that is not stopped will result in an informational return code.

Note that `bresume` does not return control to the caller until the all processes within the application have resumed or failed to resume. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for `bresume` indicates whether all processes were successfully resumed. The return value reflects the highest severity encountered across all processes.

- `ASC_success`: all processes were resumed, as expected
- `ASC_operation_failed`: some processes failed to be resumed

See Also

`attach`, `battach`, `bconnect`, `bdetach`, `bdisconnect`, `bsuspend`, `connect`, `detach`, `disconnect`, `resume`, `suspend`
3.23 bset_phase_period

Synopsis

```c
#include <Application.h>
AisStatus bset_phase_period(Phase ps, float period)
```

Parameters

- `ps` phase to be modified
- `period` new time interval between successive phase activations, in seconds

Description

This function changes the time interval between successive activations of a phase. The interval change occurs on a process by process basis for all processes within the application. Processes which do not have the phase installed result in an informational return code. Processes that are not connected result in a warning return code.

The new period is represented by a floating-point value. If the value is positive it represents the time interval in seconds. If the value is zero or positive and smaller than the minimum activation time interval, it represents the minimum activation delay time. In both cases the phase is activated immediately before setting the new interval. If the value is less than zero the phase is disabled immediately, but left in place for possible future reactivation.

Note that `bset_phase_period` does not return control to the caller until the phase period has been set or failed to be set in all processes within the application. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for `bset_phase_period` indicates whether the phase period was successfully set on all processes. The return value reflects the highest severity encountered across all processes.

- ASC_success phase period was successfully set on all processes
- ASC_operation_failed some processes failed to set the phase period

See Also

- add_phase, badd_phase, bremove_phase, get_phase_period, remove_phase, set_phase_period
### 3.24 bsignal

**Synopsis**

```cpp
#include <Application.h>
AisStatus bsignal(int unix_signal)
```

**Parameters**

- `unix_signal` Unix™ signal to be sent to every process in the application

**Description**

This function sends the specified signal to every process in the application. The process must be both connected and attached to receive the signal. The function does not return until all processes in the application have received the signal.

A signal is sent only to those processes that are connected and attached.

Note that `bsignal` does not return control to the caller until each process within the application has been signalled or failed to be signalled. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

**Return value**

The return value for `bsignal` indicates whether the AIX signal was successfully sent to all processes. The return value reflects the highest severity encountered across all processes.

- `ASC_success` signal was successfully sent to all processes
- `ASC_operation_failed` signal failed to be sent to one or more processes

**See Also**
3.25 bstart

Synopsis

```c
#include <Application.h>
AisStatus bstart(void)
```

Description

This function starts the execution of an application that has been created but not yet begun execution. Many details of this function have not yet been defined.

Note that `bstart` does not return control to the caller until the application has started or failed to start.

Return value

The return value for `bstart` indicates whether the application was successfully started.

- `ASC_success` application was started
- `ASC_operation_failed` application failed to be started

See Also

`bcreate`, `bdestroy`, `bsuspend`, `create`, `destroy`, `start`, `suspend`
3.26 bsuspend

Synopsis

#include <Application.h>

AisStatus bsuspend(void)

Description

This function suspends an application that is executing. Application suspension occurs on a
process by process basis. A tool must be both connected and attached to a process in order to
suspend process execution.

Note that bsuspend does not return control to the caller until each process within the appli-
cation has been suspended or failed to be suspended. The function Application::status(int index) may be queried to determine whether the operation succeeded or failed
on any given process.

Return value

The return value for bsuspend indicates whether all processes within the application were
successfully suspended. The return value reflects the highest severity encountered across all
processes.

ASC_success all processes were successfully suspended
ASC_operation_failed one or more processes failed to be suspended

See Also

bresume, resume, suspend
3.27 bunload_module

Synopsis

```c
#include <Application.h>
AisStatus bunload_module(ProbeModule *module)
```

Parameters

- **module**: probe module to be removed from each application process

Description

This function is currently being designed. The intent is to provide some means by which previously loaded instrumentation functions and probe classes might be removed from an application.

Note that `bunload_module` does not return control to the caller until the probe module has been removed or failed to be removed from all processes within the application. The function `Application::status(int index)` may be queried to determine whether the operation succeeded or failed on any given process.

Return value

The return value for `bunload_module` indicates whether the probe module was successfully removed from all processes. The return value reflects the highest severity encountered across all processes.

- **ASC_success**: module was successfully removed from all processes
- **ASC_operation_failed**: module could not be removed from one or more processes

See Also

- `bload_module`, `load_module`, `unload_module`
3.28 connect

Synopsis

```c
#include <Application.h>
AisStatus connect(GCBFuncType fp, GCBTagType tag)
```

Parameters

- **fp**: callback function to be invoked with each successful or failed connection to a process listed within the application
- **tag**: callback tag to be used each time the callback function is invoked

Description

Connect to all processes within an application. Connection to a process establishes a communication channel to the machine where the process resides and creates the environment within that process that allows the client to insert and remove instrumentation, alter its control flow, etc.

Note that the function submits the requests to connect the processes and returns immediately. The callback function receives notification of each connection’s success or failure.

Return value

The return value for `connect` indicates whether the requests for connection were successfully submitted, but indicates nothing about whether the requests themselves were successfully executed.

- **ASC_success**: request for connection was successfully sent
- **ASC_operation_failed**: attempt to send request to connect to this process failed

Callback Data

The callback function is invoked once for each process for which a connection is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- **ASC_success**: connection was successfully established on this process
- **ASC_operation_failed**: attempt to connect to this process failed

See Also
3.29 create

Synopsis

AisStatus create(
    const char *host,
    const char *path,
    char *const args[],
    char *const envp[],
    GCBFuncType fp,
    GCBTagType tag)

Parameters

host  host name or IP address of the control process to create the application
path  complete path to the executable program, including file name and relative or absolute directory, as appropriate
args  null terminated array of arguments to be provided to the executable
envp  null terminated array of environment variables to be provided to the executable
fp    callback function to be invoked with a successful or failed creation
tag   callback tag to be used when the callback function is invoked

Description

This function is currently being defined. It creates an application in a suspended state.
Note that create returns control immediately to the caller. It does not wait until the application
has been created. The return value indicates whether the request was successfully submitted and gives no indication whatever about the success or failure of the execution of the request.

Return value

The return value for create indicates whether the request to create an application was successfully submitted, but indicates nothing about whether the request was successfully executed.

Callback Data

The callback function is invoked once when the new application is created. When the callback
is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:
ASC_success connection was successfully established on this process
ASC_operation_failed attempt to connect to this process failed

See Also
bcreate, bdestroy, bstart, destroy, start
3.30 deactivate_probe

Synopsis

```c
#include <Application.h>
AisStatus deactivate_probe(
    short count,
    ProbeHandle *phandle,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `count`: number of probes to be deactivated
- `phandle`: array of probe handles, representing the probes, to be deactivated
- `ack_cb_fp`: acknowledgement callback function to be invoked each time all probe expressions in the array have been deactivated (or deactivation fails) within a process
- `ack_cb_tag`: tag to be used with the acknowledgement callback function

Description

This function accepts an array of probe handles as an input parameter. Each probe handle in the array represents a probe that has been installed in the application. The client sends a request to each of the processes within the application to deactivate the list of probes represented by the array. Probes are deactivated atomically for each process in the sense that the process is temporarily suspended, all probes on the list are deactivated, then the process is restarted. None of the probes in the array are left active.

`phandle` is an input array generated by an `install_probe` or `binstall_probe` call. It is supplied by the caller and must contain at least `count` elements. The `i`th element of the array is a handle, or identifier, that identifies the `i`th probe expression.

Note that `deactivate_probe` returns control immediately to the caller. It does not wait until all probes in the array have been deactivated on all processes in the application. The return value indicates whether all requests were successfully submitted and gives no indication whatever about the success or failure of the execution of those requests.

Return value

The return value for `deactivate_probe` indicates whether the deactivations were successfully submitted.

- `ASC_success`: all probe deactivations were submitted, as expected
- `ASC_operation_failed`: one or more of the probe deactivations were not submitted
Callback Data

The callback function is invoked once for each process for which a probe deactivation is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

- ASC_success: probes were successfully deactivated on this process
- ASC_operation_failed: attempt to deactivate probes on this process

See Also
### 3.31 destroy

**Synopsis**

```c
#include <Application.h>
AisStatus destroy(GCBFuncType fp, GCBTagType tag)
```

**Parameters**

- `fp`: acknowledgement callback function to be invoked for each process that is destroyed (or not destroyed)
- `tag`: tag to be used with the acknowledgement callback function

**Description**

This function destroys or terminates all processes within the application.

Note that `destroy` returns control to the caller immediately. It does not wait until all processes within the application have been destroyed. The return value indicates whether the requests were successfully submitted, but gives no indication of whether the requests themselves were successfully executed.

**Return value**

The return value for `destroy` indicates whether the terminations were successfully requested.

- `ASC_success`: all terminations were successfully requested, as expected
- `ASC_operation_failed`: one or more of the terminations were not requested

**Callback Data**

The callback function is invoked once for each process for which destruction is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success`: process was successfully destroyed
- `ASC_operation_failed`: attempt to destroy this process failed

**See Also**
3.32 detach

Synopsis

```c
#include <Application.h>

AisStatus detach(GCBFuncType fp, GCBTagType tag)
```

Parameters

- **fp**: callback function to be invoked with each successful or failed detachment from a process listed within the application.
- **tag**: callback tag to be used each time the callback function is invoked.

Description

This function detaches all processes in the application. Process control flow, such as stepping and setting break points, can only be done while a process is in an attached state. Detaching a process removes the level of process control available to the client or tool when the process is attached, but retains the process connection so probe installation, activation, removal, etc. can still take place.

Note that `detach` returns control to the caller immediately upon issuing all requests to detach from the processes. The return value indicates whether all requests were successfully submitted.

Return value

The return value for `detach` indicates whether all requests were successfully submitted.

- **ASC_success**: all detach requests were successfully submitted, as expected
- **ASC_operation_failed**: one or more requests were not submitted

Callback Data

The callback function is invoked once for each process for which detachment is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- **ASC_success**: process was successfully detached
- **ASC_operation_failed**: attempt to detach this process failed

See Also

- `attach`, `battach`, `bdetach`
3.33 disconnect

Synopsis

#include <Application.h>

AisStatus disconnect(GCBFuncType fp, GCBTagType tag)

Parameters

fp
callback function to be invoked with each successful or failed disconnection from a process listed within the application.
tag
callback tag to be used each time the callback function is invoked.

Description

Disconnect from all processes within an application. Disconnecting from an application process removes the application environment created by a connection. All instrumentation and data are removed from the application process.

Note that the function submits the requests to disconnect the processes and returns immediately. The callback function receives notification of each disconnection’s success or failure.

Return value

The return value for disconnect indicates whether the requests for disconnection were successfully submitted, but indicates nothing about whether the requests themselves were successfully executed.

Callback Data

The callback function is invoked once for each process for which disconnection is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

ASC_success process was successfully disconnected
ASC_operation_failed attempt to disconnect this process failed

See Also
3.34 execute

Synopsis

```c
#include <Application.h>
AisStatus execute(
    ProbeExp pexp,
    GBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `pexp`: probe expression to be executed in the application process
- `ack_cb_fp`: callback function to be invoked when execution succeeds or fails
- `ack_cb_tag`: callback tag to be used when the callback function is invoked

Description

This function executes a probe expression within all application processes within an application. The expression is executed once, then removed. The application process is interrupted, the expression is executed, then the process resumes execution as before the interruption.

Note that `execute` returns control to the caller immediately upon submitting its request to the daemons. It does not wait until the probe expression has been executed or failed to execute. The acknowledgement callback function receives notification of the success or failure of the execution. The callback is executed once for each process within the application.

Return value

The return value for `execute` indicates whether the request for deallocation was successfully submitted, but indicates nothing about whether the request was successfully executed.

- `ASC_success`: probe expression execution was successfully submitted
- `ASC_??`: probe expression execution was not successfully submitted

Callback Data

The callback function is invoked when execution succeeds or fails. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success`: probe expression was successfully executed
- `ASC_operation_failed`: attempt to execute the probe expression failed

See Also

- `bexecute`
3.35 free

Synopsis

#include <Application.h>

AisStatus free(
    ProbeExp pexp,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)

Parameters

pexp               dynamically allocated block of probe memory
ack_cb_fp          callback function to be invoked when deallocating the block of memory
                    succeeds or fails
ack_cb_tag         callback tag to be used when the callback function is invoked

Description

This function deallocates a block of dynamically allocated probe memory for every process in the application. The probe expression must contain only a single reference to a block of data allocated by the malloc or bmalloc functions.

Note that free returns control to the caller immediately upon submitting its request to free the data. It does not wait until the data has been deallocated or failed to deallocate. The acknowledgement callback function receives notification of the success or failure of the deallocation. The callback is executed once for each process within the application.

Return value

The return value for free indicates whether the requests for deallocation were successfully submitted, but indicates nothing about whether the requests themselves were successfully executed.

Callback Data

The callback function is invoked once for each process for which deallocation is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

ASC_success                     block of probe memory was successfully deallocated
ASC_operation_failed            attempt to deallocate memory on this process failed

See Also

bfree, bmalloc, malloc
3.36 get_count

Synopsis

    #include <Application.h>
    int get_count(void) const

Description

    This function returns the number of processes currently included in the application.

Return value

    The number of Process objects in the application.

See Also
3.37 get_process

Synopsis

    #include <Application.h>

    Process *get_process(int index) const

Parameters

    index     the position or index into the process table whose entry is to be
              retrieved.

Description

    Returns a pointer to the i\textsuperscript{th} Process object of the application.

Return value

    A pointer to the i\textsuperscript{th} Process object if the index is valid, that is, 0 \( i < \text{get\_count}() \) or a \textit{null}
    pointer if the index is not valid.

See Also
3.38 install_probe

Synopsis

```c
#include <Application.h>
AisStatus install_probe(
    short count,
    ProbeExp *probe_exp,
    InstPoint *point,
    GCBFuncType *data_cb_fp,
    GCBTagType *data_cb_tag,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag,
    ProbeHandle *phandle)
```

Parameters

- `count` : number of probe expressions to be installed, instrumentation points, data callback functions, data callback tags, and probe handles
- `probe_exp` : probe expressions to be installed
- `point` : instrumentation points where the probe expressions are to be installed
- `data_cb_fp` : callback function to process data received from the probe expression
- `data_cb_tag` : tag to be used as an argument to the data callback when it is invoked
- `ack_cb_fp` : callback function to process installation acknowledgments
- `ack_cb_tag` : tag to be used as an argument to the acknowledgement callback when it is invoked
- `phandle` : probe handles that represent the installed probe expressions

Description

This function installs probe expressions as instrumentation at specific locations within each process in the application. Probe expressions are installed atomically, in the sense that within each process either all probe expressions in the request are installed into the process, or none of the expressions are installed. There is no synchronization across processes to assure that all processes install all probes. The return value indicates whether all requests to have probes installed were successfully submitted.

`phandle` is an output array supplied by the caller that must contain at least `count` elements. The `i`th element of the array is a handle, or identifier, to be used in subsequent references to the `i`th probe expression. For example, it is needed when the client activates, deactivates or
removes a probe expression from an application or process. Phandle does not contain valid information if the installation fails.

Note that install_probe returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until all probe expressions have been installed or failed to install within all processes within the application.

Return value

The return value for install_probe indicates whether the requests for probes to be installed were successfully submitted. It gives no indication of whether those requests were successfully executed.

<table>
<thead>
<tr>
<th>ASC_success</th>
<th>all probe expression installation requests were successfully submitted</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASC_operation_failed</td>
<td>one or more of the probe expression installations failed to be requested</td>
</tr>
</tbody>
</table>

Callback Data

ack_cb_fp. The callback function is invoked once for each process for which probe installation is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

<table>
<thead>
<tr>
<th>ASC_success</th>
<th>all probes were successfully installed in this process</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASC_operation_failed</td>
<td>attempt to install probes in this process failed</td>
</tr>
</tbody>
</table>

data_cb_fp. The callback function is invoked once for each message sent from the probe. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback tag is given in the data_cb_tag array. The callback message is the data sent by the probe using the Ais_send function call.

See Also

activate_probe, bactivate_probe, bdeactivate_probe, bremove_probe, deactivate_probe, remove_probe
3.39 load_module

Synopsis

#include <Application.h>

AisStatus load_module(
    ProbeMod *module,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)

Parameters

Description

This function is currently being designed. The intent is to provide some means by which
instrumentation functions and probe classes might be loaded into an application for use by one
or more probe expressions.

Note that load_module returns control to the caller immediately upon submitting all
requests to the daemons. It does not wait until the module has been loaded or failed to load
within all processes within the application.

Return value

The return value for load_module indicates whether the requests to load the indicated
module on all processes were successfully submitted. It gives no indication of whether those
requests were successfully executed.

ASC_success       all load requests were successfully submitted
ASC_operation_failed one or more of the load operations failed to be requested

Callback Data

The callback function is invoked once for each process for which disconnection is requested.
When the callback is invoked the callback function is passed a pointer to the process as the
callback object. The callback message is the request status, of type AisStatus, which con-
tains one of the following status values:

ASC_success       objects were successfully loaded into this process
ASC_operation_failed attempt to load objects on this process failed

See Also

3.40 malloc

Synopsis

```c
#include <Application.h>

ProbeExp malloc(
    ProbeType pt,
    void *init_val,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag,
    AisStatus &stat)
```

```c
ProbeExp malloc(
    ProbeType pt,
    void *init_val,
    Phase ps,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag,
    AisStatus &stat)
```

Parameters

- **pt**: data type of the allocated data
- **init_val**: pointer to the initial value of the allocated data, or 0 if no initial value is desired
- **ps**: phase that will contain the allocated data
- **ack_cb_fp**: callback function to process acknowledgement messages
- **ack_cb_tag**: tag to be used as an argument to the acknowledgement callback when it is invoked
- **stat**: output value indicating the completion status of the function

Description

This function allocates a block of probe data in each process in the application. It returns a single probe expression that may be used to reference the allocated data. The data may be referenced in a probe expression that may be installed in any or all of the application processes where the data is allocated.
Note that `malloc` returns control to the caller immediately and does not wait until it has either succeeded or failed on all of the processes within the application. The probe expression representing the allocation is returned immediately whether or not the allocations succeed. The returned probe expression may be used as a data reference on any process where the allocation succeeds. If the data reference is used in another probe expression and the client attempts to install that probe expression in a process where the allocation failed, that probe expression will fail to install. Similarly, installation will fail if one attempts to install the probe in a process where the data was not allocated.

`Stat` indicates whether all requests for allocation were successfully submitted. If all requests are successfully submitted `stat` is given the value `ASC_success`. If some request cannot be submitted then `stat` is given the value `ASC_operation_failed`. It reflects the highest severity encountered.

**Return value**

A probe expression that may be used as a valid reference to the data on any process in which the data has been successfully allocated.

**Callback Data**

The callback function is invoked once for each process for which data allocation is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` data was successfully allocated in this process
- `ASC_operation_failed` attempt to allocate data in this process failed

**See Also**

`bfree, bmalloc, free, status`
3.41 remove_phase

Synopsis

```c
#include <Application.h>
AisStatus remove_phase(
    Phase ps,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `ps` phase description to be removed from the application
- `ack_cb_fp` callback function to process phase removal acknowledgments
- `ack_cb_tag` tag to be used as an argument to the acknowledgement callback when it is invoked

Description

This function removes a phase from the application. Data and functions associated with the phase are unaffected by removing the phase. Existing probe data cannot become associated with a phase except at the time of data allocation, so deleting a phase has the effect of permanently disassociating data from any phase.

Note that `remove_phase` returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until the phase has been removed or failed to be removed from all processes within the application.

Return value

The return value for `remove_phase` indicates whether the requests to remove the indicated phase on all processes in the application were successfully submitted. It gives no indication of whether the requests were successfully executed.

- `ASC_success` all remove requests were successfully submitted
- `ASC_operation_failed` remove operation failed to be requested to some process

Callback Data

The callback function is invoked once for each process for which phase removal is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` phase was successfully removed from this process
- `ASC_operation_failed` attempt to remove phase from this process failed
See Also

add_phase, badd_phase, bremove_phase
3.42 remove_probe

Synopsis

```c
#include <Application.h>
AisStatus remove_probe(
    short count,
    ProbeHandle *phandle,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `count` number of probe handles in the accompanying array
- `phandle` array of probe handles representing probe expressions to be removed
- `ack_cb_fp` callback function to process probe removal acknowledgments
- `ack_cb_tag` tag to be used as an argument to the callback when it is invoked

Description

This function deletes or removes probe expressions that have been installed in an application. If all probe expressions are installed and deactivated, the probe expressions are removed and a “normal” return status results. If one or more of the probe expressions are currently active, the expressions are deactivated and removed and the return status indicates there were active probes at the time of their removal. If one or more of the probes do not exist, all existing probes are removed and the return status indicates an appropriate warning. If one or more of the probe expressions exists but cannot be removed, an error results and none of the probe expressions is removed. If one or more processes are not connected, probe removal takes place within those that are connected, and a warning is issued.

`phandle` is an input array generated by an `install_probe` or `binstall_probe` call. It is supplied by the caller and must contain at least `count` elements. The `i`th element of the array is a handle, or identifier, that identifies the `i`th probe expression.

Probe expression removal is atomic in the sense that all probe expressions are removed from a given process or none are. When probes are removed from a process the process is temporarily suspended, all indicated probes are removed, and the process is resumed. Probe expressions are removed in a process by process basis. There is no synchronization between processes to guarantee that all indicated expressions are removed from all processes. One process may succeed while another one fails.

Note that `remove_probe` returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until the probes have been removed or failed to be removed from all processes within the application.
Return value

The return value for remove_probe indicates whether the requests to remove the indicated probes on all processes in the application were successfully submitted. It gives no indication of whether the requests were successfully executed.

- ASC_success: all remove requests were successfully submitted
- ASC_operation_failed: remove operation failed to be requested to some process

Callback Data

The callback function is invoked once for each process for which probe removal is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

- ASC_success: probes were successfully removed from this process
- ASC_operation_failed: attempt to remove probes from this process failed

See Also

activate_probe, bactivate_probe, bdeactivate_probe, binstall_probe, bremove_probe, deactivate_probe, install_probe
### 3.43 remove_process

**Synopsis**

```c
#include <Application.h>

AisStatus remove_process(int i)
```

**Parameters**

- `i` position or index into the process table whose entry is to be removed.

**Description**

This function removes the `i`th Process object of the application. Parameter `i` must reflect a valid index, that is, that is, `0 ≤ i < get_count()`. The process itself is not altered or affected in any way.

The index of a process is not guaranteed to remain invariant when new processes are added to or removed from an application. The index does remain invariant otherwise.

**Return value**

The return value for `remove_process` indicates whether the process was successfully removed. The return value reflects the highest severity encountered across all processes.

- `ASC_success` process was removed
- `ASC_operation_failed` index was out of bounds

**See Also**

- attach, battach, bconnect, bdetach, bdisconnect, bsuspend, connect, detach, disconnect, resume, suspend
3.44 resume

Synopsis

```c
#include <Application.h>
AisStatus resume(GCBFuncType ack_cb_fp, GCBTagType ack_cb_tag)
```

Parameters

- `ack_cb_fp` callback function to process process resumption acknowledgments
- `ack_cb_tag` tag to be used as an argument to the callback when it is invoked

Description

This function resumes execution of an application that has been temporarily suspended by a `suspend` or `bsuspend` function. Execution resumption occurs on a process by process basis. A process must be connected, attached and suspended for it to be resumed. A process that is not connected or not attached will result in a warning return code. A process that is not suspended will result in an informational return code.

Note that `resume` returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until the processes have resumed or failed to resume.

Return value

The return value for `resume` indicates whether all requests to resume process execution were successfully submitted. It gives no indication of whether the requests were successfully executed.

- `ASC_success` all request to resume execution were successfully submitted
- `ASC_operation_failed` resume operation failed to be requested for some process

Callback Data

The callback function is invoked once for each process to be resumed. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` process was successfully resumed
- `ASC_operation_failed` attempt to resume this process failed

<tr>
<td>ack_cb_fp</td>
<td>callback function to process phase acknowledgments</td>
</tr>
<tr>
<td>ack_cb_tag</td>
<td>tag to be used as an argument to the callback when it is invoked</td>
</tr>
</tbody>
</table>

Description

This function changes the time interval between successive activations of a phase. The interval change occurs on a process by process basis for all processes within the application. Processes which do not have the phase installed result in an informational return code. Processes that are not connected result in a warning return code.

The new period is represented by a floating-point value. If the value is positive it represents the time interval in seconds. If the value is zero or positive and smaller than the minimum activation time interval, it represents the minimum activation time interval. In both cases the phase is activated immediately upon setting the new interval. If the value is less than zero the phase is disabled immediately, but left in place for possible future reactivation.

Note that set_phase_period returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until the phase period has been set or failed to be set within all processes within the application.

Return value

The return value for set_phase_period indicates whether all requests to set the phase period were successfully submitted. It gives no indication of whether the requests were successfully executed.

<table>

<tbody>
<tr>
<td>ASC_success</td>
<td>all requests to set the phase period were submitted</td>
</tr>
<tr>
<td>ASC_operation_failed</td>
<td>set phase period failed to be requested for some process</td>
</tr>
</tbody>
</table>
Callback Data

The callback function is invoked once for each process for which setting the new period for a phase is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type Ais_Status, which contains one of the following status values:

- **ASC_success**: phase period was successfully set
- **ASC_operation_failed**: attempt to set the phase period on this process failed

3.46 signal

Synopsis

```c
#include <Application.h>

AisStatus signal(
    int unix_signal,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `unix_signal` Unix™ signal to be sent to every process in the application
- `ack_cb_fp` callback function to process signal acknowledgments
- `ack_cb_tag` tag to be used as an argument to the callback when it is invoked

Description

This function sends the specified signal to every process in the application. The process must be both connected and attached to receive the signal.

A signal is sent only to those processes that are connected and attached.

Note that `signal` returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until processes within the application have been signaled or failed to be signalled.

Return value

The return value for `signal` indicates whether all requests to signal processes were successfully submitted. It gives no indication of whether the requests were successfully executed.

- `ASC_success` all requests to signal the processes were submitted
- `ASC_operation_failed` signalling failed to be requested for some process

Callback Data

The callback function is invoked once for each process for which signalling is requested.

When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` process was successfully signaled
- `ASC_operation_failed` attempt to signal this process failed

See Also
3.47 start

Synopsis

```c
#include <Application.h>
AisStatus start(GCBFuncType ack_cb_fp, GCBTagType ack_cb_tag)
```

Parameters

- `ack_cb_fp` callback function to process start acknowledgments
- `ack_cb_tag` tag to be used as an argument to the callback when it is invoked

Description

This function is currently being designed. This function starts the execution of an application that has been created but not yet begun execution.

Note that `start` returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the application has been started or failed to be started.

Return value

The return value for `start` indicates whether the request to start the application was successfully submitted. It gives no indication of whether the request was successfully executed.

- `ASC_success` request to start the application was submitted
- `ASC_operation_failed` start failed to be requested

Callback Data

The callback function is invoked once, when the acknowledgement of the completion of this operation is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` application was successfully started
- `ASC_operation_failed` attempt to start this application failed

See Also
### 3.48 status

**Synopsis**

```c
#include <Application.h>
AisStatus status(int i)
```

**Parameters**

- `i`: position or index into the process table whose status is to be queried.

**Description**

This function returns status for the `i`th Process object of the application. Parameter `i` must reflect a valid index, that is, `0 ≤ i < get_count()`. The returned value reflects the status value of the most recently executed blocking call.

**Return value**

Interpretation of the return value for `status` is determined by the most recent blocking call that was executed.

- `ASC_invalid_index`: index does not reflect a valid index

**See Also**
3.49 suspend

Synopsis

```
#include <Application.h>
AisStatus suspend(GCBFuncType fp, GCBTagType tag)
```

Parameters

- **fp**: callback function to process suspend acknowledgments
- **tag**: tag to be used as an argument to the callback when it is invoked

Description

This function suspends an application that is executing. Application suspension occurs on a process by process basis. A tool must be both connected and attached to a process in order to suspend process execution.

Note that `suspend` returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until processes within the application have been suspended or failed to be suspended.

Return value

The return value for `suspend` indicates whether all requests to suspend processes were successfully submitted. It gives no indication of whether the requests were successfully executed.

- **ASC_success**: all requests to signal the processes were submitted
- **ASC_operation_failed**: signalling failed to be requested for some process

Callback Data

The callback function is invoked once for each process for which suspension is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- **ASC_success**: process was successfully suspended
- **ASC_operation_failed**: attempt to suspend this process failed

3.50 unload_module

Synopsis

```
#include <Application.h>
AisStatus unload_module(
    ProbeMod *module,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `ack_cb_fp`: callback function to process module removal acknowledgments
- `ack_cb_tag`: tag to be used as an argument to the acknowledgement callback when it is invoked

Description

This function is currently being designed. The intent is to provide some means by which previously loaded instrumentation functions and probe classes might be removed from an application.

Note that `unload_module` returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until the module has been removed or failed to be removed from all processes within the application.

Return value

The return value for `unload_module` indicates whether the requests to remove the indicated module on all processes were successfully submitted. It gives no indication of whether those requests were successfully executed.

- `ASC_success`: all remove requests were successfully submitted
- `ASC_operation_failed`: one or more of the remove operations failed to be requested

Callback Data

The callback function is invoked once for each process for which object removal is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success`: module was successfully removed from this process
- `ASC_operation_failed`: attempt to remove module from this process failed

See Also

`bload_module`, `bunload_module`, `load_module`
4.0 class GenCallBack

4.1 Supporting Data Types

4.1.1 GCBSysType

Synopsis

```c
struct GCBSysType {
    int msg_socket;    // socket over which msg was received
    int msg_type;      // message type
    int msg_size;      // size of the message sent
}
```

Description

This structure is provided as the data type of an input parameter to each callback function as it is invoked. The structure is filled in by the system each time a callback is invoked as the system prepares to invoke the callback.

4.1.2 GCBTagType

Synopsis

```c
typedef void *GCBTagType
```

Description

This data type is used by the tag parameter of a callback function. The tag parameter is supplied by the user at the time the callback is registered. Tags are declared as a `void *` to provide adequate space for the tag to be a pointer. The tag itself only has meaning to the callback function and is neither read nor written by the callback system.

4.1.3 GCBObjType

Synopsis

```c
typedef void *GCBObjType
```

Description

This data type is used by the object parameter of a callback function. The object parameter is supplied by the system at the time the callback is registered. The object parameter represents a pointer to the object that invokes the asynchronous operation that causes the callback to be invoked. The callback function must know the actual data type of the invoking object and explicitly cast the pointer to be of that type.
4.1.4 GCBMsgType

Synopsis

typedef void *GCBMsgType

Description

This data type is used by the message parameter of a callback function. The message parameter is supplied by the system at the time the callback is invoked. It is the arrival of this message that causes the callback function to be invoked. The callback function must know the actual data type of the message and explicitly cast the pointer to be of that type.

4.1.5 GCBFuncType

Synopsis

typedef void (*GCBFuncType)(
    GCBSysType sys,       // system data structure
    GCBTagType tag,       // user-supplied tag value
    GCBObjType obj,       // object that registers the callback
    GCBMsgType msg)       // activating or invoking message

Description

This data type represents a pointer to the callback function. Explicit, user-supplied callback functions are used in all asynchronous function calls.
5.0 class InstPoint

5.1 Supporting Data Types

5.1.1 InstPtLocation

Synopsis

```cpp
#include <InstPoint.h>
enum InstPtLocation {
    IPL_invalid,
    IPL_before,
    IPL_after,
    IPL_replace,
    IPL_LAST_LOCATION
};
```

Description

This enumeration type is used to describe the location of instrumentation relative to the instruction being instrumented. Not all locations are valid with all instrumentation point types. Instrumentation may be placed before the instruction, after the instruction, or the requested code may in some cases replace the instruction in question. Instrumentation points that are not attached to a location within an application or process, perhaps because they were created by a default constructor, are invalid.
5.1.2 InstPtType

Synopsis

```
#include <InstPoint.h>
enum InstPtType {
    IPT_invalid,
    IPT_function_entry,
    IPT_function_exit,
    IPT_function_call,
    IPT_loop_entry,
    IPT_loop_exit,
    IPT_block_entry,
    IPT_block_exit,
    IPT_statement_entry,
    IPT_statement_exit,
    IPT_instruction,
    IPT_LAST_TYPE
}
```

Description

This enumeration type describes the type of location that may be instrumented. Not all will be available within a given source object. Availability depends on source object type and options used when compiling the application process.

See Also

class SourceObj
5.2 Constructors

Synopsis

```c
#include <InstPoint.h>
InstPoint (void)
InstPoint (const InstPoint &copy)
```

Parameters

- `copy` object to be duplicated in the copy constructor

Description

Two constructors are provided with this class -- a default constructor and a copy constructor. The default constructor is able to create storage, marked as containing invalid instrumentation points, that may later be assigned through an assignment from a valid instrumentation point. The copy constructor performs a similar operation to assignment, but operates on an uninitialized object.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node

See Also
5.3 get_container

Synopsis

#include <InstPoint.h>

SourceObj get_container(void) const

Description

This function returns the source object that contains the instrumentation point. This allows a tool to start with an instrumentation point and explore the context in which it occurs, such as the function and module in which the instrumentation point resides.

Return value

Source object that contains the instrumentation point.

See Also
5.4 get_function

Synopsis

```
#include <InstPoint.h>
SourceObj get_function(void) const
```

Description

When the instrumentation point refers to a subroutine or function call site, this function returns a description of the function being called. When the instrumentation point does not refer to a call site, this function returns a source object marked as invalid.

Return value

Source object describing the function or marked as invalid.

See Also

get_type
5.5 get_line

Synopsis

#include <InstPoint.h>

int get_line(void) const

Description

This function returns the approximate line number in source where the instrumentation point occurs. If the instrumentation point is invalid, this function returns a value of -1.

Return value

Approximate line number in source or -1.

See Also
5.6 get_location

Synopsis

#include <InstPoint.h>
InstPtLocation get_location(void) const

Description

This function returns the location of the instrumentation relative to the instrumentation point. Possible locations are: before, after, replace, and invalid. If the location is before, then instrumentation installed using this instrumentation point will occur immediately before the instruction is executed. If after, then instrumentation will be installed immediately after the instruction. If replace, the instrumentation will replace the instruction. When the instrumentation point is not attached to a valid location within a process, the return value is invalid.

Return value

IPL_invalid instrumentation point is not attached to a valid location
IPL_before instrumentation is placed before the indicated instruction
IPL_after instrumentation is placed after the indicated instruction
IPL_replace instrumentation replaced the indicated instruction

See Also
### 5.7 get_type

**Synopsis**

```c
#include <InstPoint.h>

InstPtType get_type(void) const
```

**Description**

This function returns the type of this instrumentation point, such as beginning or end of a subroutine, at a function call site, *etc.*

**Return value**

Type of instrumentation point.

**See Also**
5.8 operator =

Synopsis

```
#include <InstPoint.h>

InstPoint &operator = (const InstPoint &copy)
```

Parameters

- **copy**
  object to be duplicated in the assignment operator

Description

This function copies the argument over the top of the invoking object.

Return value

Reference to the invoking object.

Parameters

Description

Return value
7.0 class Phase

Phases represent the client visible control mechanism for time-initiated instrumentation. In other words, phases are used to control time-sampled instrumentation. Phases are activated, or invoked, when an interval timer expires. The interval timer uses the SIGPROF signal to activate the phase, so applications that use SIGPROF cannot be instrumented with phases.

When a phase is activated it executes its begin function to initialize any data that may be used during the rest of the phase. If the begin function sends any messages back to the client those messages invoke the begin callback function. The begin callback function is invoked once per message sent. After the begin function has completed the data function is then executed, once per datum of probe data associated with the phase. Data is associated with a phase through the Application::malloc or Process::malloc functions. Any messages sent to the client by the data function are handled on the client by the data callback function. When the data function finishes execution for the last datum, the end function is then executed to perform any necessary clean-up operations. Messages sent by the end function are handled by the end callback.

To fully understand phases it is important to understand that the Phase object on the client is a data structure that represents the actual phase. The actual phase resides within the instrumented application process. Certain operations, such as malloc, can alter the actual phase in ways that are not reflected within the client data structure. This affects the behavior of the client data structure in subtle ways. In order to provide the most useful abstraction for phases, the default constructor and the copy constructor create new client data structures but they do not create unique phases. As a result, “Phase p1, p2;” creates a situation where “p1 == p2” is regarded as true. Similarly, the sequence “Phase p1(f1, f2, t); Phase p2 = p1;” also results in “p1 == p2” evaluating to true. Similar behavior results when the assignment operator, operator =, is used.

In contrast, the standard constructors create unique phases even when the parameters used in the constructors are identical. Thus “Phase p1(f1, f2, t), p2(f1, f2, t);” results in a situation where “p1 == p2” would evaluate to false rather than true. This possibly counter-intuitive behavior is necessary to allow end-user tools to manage separate groups of data on separate timers.
7.1 Constructors

Synopsis

#include <Phase.h>
Phase(void)
Phase(const Phase &copy)

Phase(float period,
        ProbeExp data_func,
        GCBFuncType data_cb,
        GCBTagType data_tg)

Phase(float period,
        ProbeType probe,
        ProbeExp begin_func,
        GCBFuncType begin_cb,
        GCBTagType begin_tg,
        ProbeExp data_func,
        GCBFuncType data_cb,
        GCBTagType data_tg,
        ProbeExp end_func,
        GCBFuncType end_cb,
        GCBTagType end_tg)

Parameters

copy phase that will be duplicated in a copy constructor
period time interval, in seconds, between successive invocations of the phase
begin_func begin function, executed once upon invocation of the phase
begin_cb begin callback, to which any begin function messages are addressed
begin_tag callback tag for the begin callback begin_cb
data_func function that, each time the phase is invoked, is executed once for each
datum associated with the phase
class Phase

data_cb
    callback function to which any data function messages are addressed

data_tag
    callback tag for the data function callback data_cb

data_func
    end function, executed once per invocation of the phase after the data function has completed its series of executions

data_end
    end callback, to which any end function messages are addressed

data_end_tag
    callback tag for the end callback data_end

Description

The default constructor creates an empty phase whose period, functions, callbacks and tags are all set to 0. The default constructor is invoked when uninitialized phases are created, such as in arrays of phases. Objects within the array can be overwritten using an assignment operator (operator =).

The copy constructor is used to transfer the contents of an initialized object (the copy parameter) to an uninitialized object.

The standard constructors create a new phase and new phase data structure, and initialize the data structure according to the parameters that are provided. The function prototypes are:

- void begin_func(void *msg_handle)
- void data_func(void *msg_handle, void *data)
- void end_func(void *msg_handle)

Exceptions

ASC_insufficient_memory not enough memory to create a new node

See Also

7.2 operator =

Synopsis

```c
#include <Phase.h>
Phase &operator = (const Phase &rhs)
```

Parameters

- `rhs` right operand

Description

This function assigns the value of the right operand to the invoking object. The left operand is the invoking object. For example, “Phase rhs, lhs; ... lhs = rhs;” assigns the value of `rhs` to `lhs`. Then one can be used interchangeably with the other.

Note that assignment is different from creating two phases using the same input values. For example, “Phase p1(x, y, z), p2(x, y, z);” gives two independent phases even though they have exactly the same arguments. Loading `p1` into a process and later unloading `p1` from the same process is, of course, a valid operation. Loading `p1` into a process and later unloading `p2` from the same process as if they were the same phase is invalid, since `p2` represents a different phase with coincidentally the same values.

Return value

A reference to the invoking object (i.e., the left operand).

See Also
7.3 operator ==

Synopsis

```c
#include <Phase.h>

int operator == (const Phase &compare)
```

Parameters

- `compare` phase to be compared against the invoking object

Description

This function compares two phases for equivalence. If the two objects represent the same phase, this function returns 1. Otherwise it returns 0. For example, “Phase rhs, lhs; ... lhs = rhs;” gives a situation where “rhs == lhs” is true, and operator == returns 1. But “Phase p1(x, y, z), p2(x, y, z);” gives a situation where the value of “p1 == p2” is not true, even though they were both constructed with the same values, and operator == returns 0.

Return value

This function returns 1 if the two objects are equivalent, 0 otherwise.

See Also
7.4 operator !=

Synopsis

```
#include <Phase.h>

int operator != (const Phase &compare)
```

Parameters

- `compare` phase to be compared against the invoking object

Description

This function compares two phases for equivalence. If the two objects represent the same phase, this function returns 0. Otherwise it returns 1. For example, `Phase rhs, lhs; ... lhs = rhs;` gives a situation where `rhs != lhs` is false, and `operator !=` returns 0. But `Phase p1(x, y, z), p2(x, y, z);` gives a situation where the value of `p1 != p2` is true, even though they were both constructed with the same values, and `operator !=` returns 1.

Return value

This function returns 0 if the two objects are equivalent, 1 otherwise.

**Return value**
9.0 class ProbeExp

9.1 Supporting Data Types

9.1.1 Primitive Data Types

Synopsis

```c
typedef char          int8_t
typedef short         int16_t
typedef int           int32_t
typedef long long     int64_t
typedef unsigned char uint8_t
typedef unsigned short uint16_t
typedef unsigned int  uint32_t
typedef unsigned long long uint64_t
typedef float         float32_t
typedef double        float64_t
```

Description

This collection of data types represents the primitive data types supported at some level by probe expressions. These are client data types that represent entities used in a probe expression inside an application process. Not all data types are given the same level of support. 32-bit integers are given the greatest level of support, with arithmetic, logical, bitwise, relational and assignment operators. Although pointer values can be manipulated in probe expressions, they are not given a separate data type on the client, but are themselves represented by probe expressions. More complex data types may be allocated for use in probe expressions, but operators that make use of such values are quite limited.

9.1.2 CodeExpNodeType

Synopsis

```c
enum CodeExpNodeType {
    CEN_address_op,       // the address of      -- &x
    CEN_and_op,           // bitwise “and”        -- x & y
    CEN_andand_op,        // logical “and”         -- x && y
    CEN_andeq_op,         // bitwise “and”        -- x & eq y
```

CEN_if_stmt, // if stmt -- if (x) y
CEN_null_stmt, // null/empty stmt -- ;
CEN.Undef_node, // undefined node
CEN_LAST_TYPE // last node type marker

Description

The CodeExpNodeType enumeration data type represents the various operators and operands that may be found in probe expressions. Probe expressions are structured as abstract syntax trees. Expressions are represented with binary operators as a typed node with the left as the left sub-tree, and the right as the right sub-tree.
9.2 Constructors

Synopsis

ProbeExp(void)
ProbeExp(int8_t scalar)
ProbeExp(int16_t scalar)
ProbeExp(int32_t scalar)
ProbeExp(int64_t scalar)
ProbeExp(uint8_t scalar)
ProbeExp(uint16_t scalar)
ProbeExp(uint32_t scalar)
ProbeExp(uint64_t scalar)
ProbeExp(float32_t scalar)
ProbeExp(float64_t scalar)
ProbeExp(const char *string)
ProbeExp(const ProbeExp &copy)

Parameters

scalar single value of some primitive data type
string null terminated array of signed 8-bit integers, or characters
copy probe expression object that will be duplicated in a copy constructor

Description

All of the above constructors create a new node that may be used as a sub-tree in a larger probe expression. Each of the public constructors, with the exception of the copy constructor, create terminal nodes. To create an expression containing operators one must use the ProbeExp operator that corresponds to the desired action. The ProbeExp operator constructs the probe expression and performs a validity check. The probe expression may then be installed and activated in an application, at which time additional checks are made to ensure data references are valid within the process.

The copy constructor duplicates the argument, but copies argument children by reference. In other words, it does not duplicate sub-expressions contained as children of copy. Instead it duplicates a pointer to the sub-expression and updates the appropriate reference counter.

Exceptions

ASC_insufficient_memory not enough memory to create a new node
### 9.3 address

**Synopsis**

#include <ProbeExp.h>

ProbeExp address(void)

**Description**

This function creates a probe expression that represents taking the address of the object in application memory represented by the invoking object. The operand must be an object in application memory. For example, “ProbeExp exp = obj.address();” would create an expression exp that represents the address of obj. The expression exp could then be used as a sub-expression in an assignment or other type of statement or expression.

Computing the address is valid for any object regardless of data type, but the expression must represent an object in memory. The data type of the result of executing the expression is a pointer.

This expression may be executed on the application process only after it has been installed and activated.

**Return value**

Probe expression representing the address of the object represented by the operand.

**Exceptions**

ASC_insufficient_memory insufficient memory to create a new node
ASC_invalid_expression invoking object does not represent an object in memory

**See Also**
9.4 assign

Synopsis

```c
#include <ProbeExp.h>

ProbeExp assign(const ProbeExp &rhs) const
```

Parameters

- `rhs` right, or value expression, of the assignment

Description

This function creates an expression where the right operand is evaluated and stored in the location indicated by the left operand. The left operand is represented by the invoking object. For example, “`ProbeExp exp = lhs.assign(rhs);`” would create an expression `exp` that represents evaluating `rhs` and storing its value in the location represented by `lhs`. It is essential that `lhs` represent an object in memory.

This expression may be executed on the application process only after it has been installed and activated.

Return value

- Probe expression representing the assignment of a value to an object.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of `rhs` (the value assigned) did not match the data type of the invoking object (location assigned to)

See Also
9.5 call

Synopsis

```c
#include <ProbeExp.h>

ProbeExp call(short count, ProbeExp *args)
```

Parameters

- **count**: count of arguments or parameters passed to the function being called
- **args**: array of arguments or parameters passed to the function being called

Description

This function creates a probe expression that represents a function call. The invoking object represents the function to be called in the application process. For example, the expression “`ProbeExp exp = foo.call(count, args);`” would create an expression `exp` that represents calling a function represented by `foo`. This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing a call to a function.

Exceptions

- **ASC_insufficient_memory**: insufficient memory to create a new node
- **ASC_invalid_expression**: one or more arguments to the function does not represent valid a probe expression, either because the expression is ill formed, the expression data type does not match the function argument data type, or data referenced in the expression does not reside on the process

See Also
9.6 get_data_type

Synopsis

#include <ProbeExp.h>

ProbeType get_data_type(void) const

Description

This function returns the data type of the probe expression.

Return value

Data type of the probe expression.

See Also
9.7 get_node_type

Synopsis

    #include <ProbeExp.h>
    CodeExpNodeType get_node_type(void) const

Description

This function returns the type of node at the root of the probe expression tree. Nodes in a tree represent operators or operands in an executable expression.

Return value

Type of operator or operand at the root of the probe expression tree.

See Also
9.8 has *

Synopsis

```c
int has_int8(void) const  
int has_int16(void) const  
int has_int32(void) const  
int has_int64(void) const  
int has_int(void) const    
int has_uint8(void) const  
int has_uint16(void) const  
int has_uint32(void) const  
int has_uint64(void) const  
int has_uint(void) const    
int has_float32(void) const  
int has_float64(void) const  
int has_float(void) const    
int has_string(void) const  
int has_name(void) const    
int has_text(void) const    
int has_children(void) const  
int has_left(void) const    
int has_right(void) const   
int has_center(void) const  
```

Description

This family of functions returns a boolean indicator of whether the node being queried represents a datum with the data type in question. Thus `has_int32` will return 1 if the node represents a constant of data type `int32_t`.

Return value

See Also
### 9.9 ifelse

**Synopsis**

```c
#include <ProbeExp.h>

ProbeExp ifelse(const ProbeExp &te) const
ProbeExp ifelse(const ProbeExp &te, const ProbeExp &ee) const
```

**Parameters**

- `te`  
  "then" expression, or expression executed when condition is true

- `ee`  
  "else" expression, or expression executed when condition is false

**Description**

This function creates a probe expression that represents a conditional statement. The invoking object represents the condition to be tested. If the test evaluates to a non-zero value, the expression represented by `te` is executed. If the test evaluates to zero and `ee` is not supplied, execution continues past the conditional. If the test evaluates to zero and `ee` is supplied, then the expression represented by `ee` is executed. For example, `
```c
ProbeExp exp = ce.ifeelse(te);
```
```c
``` would create an expression `exp` that represents a conditional statement. The conditional expression to be tested is represented by `ce`, and the expression to be executed should that condition be evaluated to true (any non-zero integer value) is represented by `te`. This expression may be executed on the application process only after it has been installed and activated.

**Return value**

Probe expression representing a conditional statement.

**Exceptions**

- `ASC_insufficient_memory`  
  insufficient memory to create a new node

- `ASC_invalid_expression`  
  data type of the invoking object is not an integer or pointer

**See Also**
## 9.10 is\_same\_as

**Synopsis**

```c
#include <ProbeExp.h>

int is_same_as(const ProbeExp &compare) const
```

**Parameters**

- `compare` right hand side of comparison

**Description**

This function compares two probe expressions for equivalence. If the invoking object has the same structure as the probe expression it is compared against, this function returns 1. If the structure is different in some way, or the expressions are similar in structure but have different values at corresponding nodes, it returns 0.

**Return value**

This function returns 1 when the expressions are equivalent, otherwise 0.

**See Also**
9.11 operator + (binary)

Synopsis

```c
#include <ProbeExp.h>

ProbeExp operator + (const ProbeExp &rhs)
```

Parameters

- `rhs` : right operand

Description

This function creates a probe expression that represents the addition of two operands. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, “`ProbeExp exp = lhs + rhs;`” would create an expression `exp` that represents the addition of two values, `lhs` and `rhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Addition is only valid when both operands are integers, or one operand is an integer and one is a pointer. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer. When one operand is a pointer, it has the usual meaning associated with pointer arithmetic as defined in C/C++, and the data type associated with the result is a pointer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the addition of two operands.

Exceptions

- `ASC_insufficient_memory` : insufficient memory to create a new node
- `ASC_invalid_expression` : data type of one or both operands is inappropriate

See Also
9.12 operator + (unary)

Synopsis

```c
#include <ProbeExp.h>
ProbeExp operator + (void)
```

Description

This function is effectively a no-op. It simply returns the value of its operand.

Return value

Probe expression representing the left operand.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node

See Also
9.13 operator +=

Synopsis

```c
#include <ProbeExp.h>

ProbeExp operator += (const ProbeExp &rhs)
```

Parameters

- `rhs`: right operand

Description

This function creates a probe expression that represents the addition of two operands, and its subsequent storage of the result into the invoking object. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, the expression

```
ProbeExp exp = lhs += rhs;
```

would create an expression `exp` that represents the addition of two values, `lhs` and `rhs`, and its assignment to `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Addition is only valid when both operands are integers, or the left operand is a pointer and the right operand is an integer. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer. When `lhs` is a pointer, it has the usual meaning associated with pointer arithmetic as defined in C/C++ and the data type of the result of executing the expression is a pointer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the addition of two operands and assignment of the result.

Exceptions

- `ASC_insufficient_memory`: insufficient memory to create a new node
- `ASC_invalid_expression`: data type of one or both operands is inappropriate

See Also
9.14 operator ++ (prefix)

Synopsis

```c
#include <ProbeExp.h>

ProbeExp operator ++ (void)
```

Description

This function creates a probe expression that represents the increment of an integer operand. The operand is the invoking object. The operand must be an expression that represents an object in memory. The result of the operation is the value of the operand after the increment takes place. For example, ```ProbeExp exp = ++rhs;``` would create an expression ```exp``` that represents incrementing ```rhs``` by one. The expression ```exp``` could then be used as a sub-expression in an assignment or other type of statement or expression.

Increment is only valid when the operand is a signed integer or a pointer. Any other operand data type is invalid. When the operand is an integer it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer. When ```rhs``` is a pointer, it has the usual meaning associated with pointer arithmetic as defined in C/C++ and the data type of the result of executing the expression is a pointer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the addition of one to an operand and assignment of the result.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of the operand is inappropriate

See Also
9.15 operator ++ (postfix)

Synopsis

```
#include <ProbeExp.h>

ProbeExp operator ++ (int zero)
```

Parameters

```
zero        constant integer zero
```

Description

This function creates a probe expression that represents the increment of an integer operand. The operand is the invoking object. The operand must be an expression that represents an object in memory. The result of the operation is the value of the operand before the increment takes place. For example, “ProbeExp exp = lhs++;” would create an expression exp that represents incrementing lhs by one. The expression exp could then be used as a sub-expression in an assignment or other type of statement or expression.

Increment is only valid when the operand is a signed integer or a pointer. Any other operand data type is invalid. When the operand is an integer it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer. When lhs is a pointer, it has the usual meaning associated with pointer arithmetic as defined in C/C++ and the data type of the result of executing the expression is a pointer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the addition of one to an operand and assignment of the result.

Exceptions

```
ASC_insufficient_memory  insufficient memory to create a new node
ASC_invalid_expression   data type of the operand is inappropriate
```

See Also
9.16 operator - (binary)

Synopsis

```
#include <ProbeExp.h>

ProbeExp operator - (const ProbeExp &rhs)
```

Parameters

- `rhs`: right operand

Description

This function creates a probe expression that represents the subtraction of two operands. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, "`ProbeExp exp = lhs - rhs;`" would create an expression `exp` that represents the subtraction of `rhs` from `lhs`. The expression `exp` could then be used as a subexpression in an assignment or other type of statement or expression.

Subtraction is only valid when both operands are integers, or the left operand is a pointer and the right operand is an integer, or both operands are pointers of the same type. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer. When one or both operand is a pointer, it has the usual meaning associated with pointer arithmetic as defined in C/C++, and the data type associated with the result is a pointer. When both operands are pointers, it has the usual meaning associated with pointer subtraction as defined in C/C++, and the data type associated with the result is a signed integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the subtraction of two operands.

Exceptions

- `ASC_insufficient_memory`: insufficient memory to create a new node
- `ASC_invalid_expression`: data type of one or both operands is inappropriate

See Also
9.17 **operator - (unary)**

**Synopsis**

```c
#include <ProbeExp.h>

ProbeExp operator - (void)
```

**Description**

This function creates a probe expression that represents the arithmetic negation of an operand. The right operand represents the invoking object. The operand may be an object in memory or an expression that evaluates to a value. For example, “`ProbeExp exp = - rhs;`” would create an expression `exp` that represents the negation of `rhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Negation is only valid when the operand is a signed integer. Any other operand data type is invalid. When the operand is an integer it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

**Return value**

Probe expression representing the arithmetic negation of an operand.

**Exceptions**

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of the operand is inappropriate

**See Also**
9.18 operator -=

Synopsis

```c
#include <ProbeExp.h>

ProbeExp operator -= (const ProbeExp &rhs)
```

Parameters

- `rhs` right operand

Description

This function creates a probe expression that represents the subtraction of two operands, and its subsequent storage of the result into the invoking object. The left operand represents the invoking object, while the argument `rhs` represents the right operand. The left operand must be an object in memory, while the right operand may be an object in memory or an expression that evaluate to a value. For example, `ProbeExp exp = lhs -= rhs;` would create an expression `exp` that represents the subtraction of two values, `lhs` and `rhs`, and its assignment to `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Subtraction is only valid when both operands are integers, or the left operand is pointer and the right operand is an integer. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer. When `lhs` is a pointer, it has the usual meaning associated with pointer arithmetic as defined in C/ C++ and the data type of the result of executing the expression is a pointer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the subtraction of two operands and assignment of the result.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of one or both operands is inappropriate

See Also
9.19 operator -- (prefix)

Synopsis

```c
#include <ProbeExp.h>

ProbeExp operator -- (void)
```

Description

This function creates a probe expression that represents the decrement of an integer operand. The operand is the invoking object. The operand must be an expression that represents an object in memory. The result of the operation is the value of the operand after the decrement takes place. For example, ```ProbeExp exp = --rhs;``` would create an expression `exp` that represents decrementing `rhs` by one. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Decrement is only valid when the operand is a signed integer or a pointer. Any other operand data type is invalid. When the operand is an integer it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer. When `rhs` is a pointer, it has the usual meaning associated with pointer arithmetic as defined in C/C++ and the data type of the result of executing the expression is a pointer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the subtraction of one from an operand and assignment of the result.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of the operand is inappropriate

See Also
9.20 operator -- (postfix)

Synopsis

    #include <ProbeExp.h>
    ProbeExp operator -- (int zero)

Parameters

    zero        constant integer zero

Description

    This function creates a probe expression that represents the decrement of an integer operand. The operand is the invoking object. The operand must be an expression that represents an object in memory. The result of the operation is the value of the operand before the decrement takes place. For example, “ProbeExp exp = lhs--;” would create an expression exp that represents decrementing lhs by one. The expression exp could then be used as a sub-expression in an assignment or other type of statement or expression.

    Decrement is only valid when the operand is a signed integer or a pointer. Any other operand data type is invalid. When the operand is an integer it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer. When lhs is a pointer, it has the usual meaning associated with pointer arithmetic as defined in C/C++ and the data type of the result of executing the expression is a pointer.

    This expression may be executed on the application process only after it has been installed and activated.

Return value

    Probe expression representing the subtraction of one from an operand and assignment of the result.

Exceptions

    ASC_insufficient_memory   insufficient memory to create a new node
    ASC_invalid_expression    data type of the operand is inappropriate

See Also
9.21 operator * (binary)

Synopsis

```
#include <ProbeExp.h>

ProbeExp operator * (const ProbeExp &rhs)
```

Parameters

- rhs 
  right operand

Description

This function creates a probe expression that represents the multiplication of two operands. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, “`ProbeExp exp = lhs * rhs;`” would create an expression `exp` that represents the multiplication of `rhs` by `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Multiplication is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the multiplication of two operands.

Exceptions

- ASC_insufficient_memory   insufficient memory to create a new node
- ASC_invalid_expression    data type of one or both operands is inappropriate

See Also

9.22 operator *(unary)

Synopsis

```c
#include <ProbeExp.h>
ProbeExp operator * (void)
```

Description

This function creates a probe expression that represents the dereferencing of a pointer operand. The right operand represents the invoking object. The operand may be an object in memory or an expression that evaluates to a value. For example, “ProbeExp exp = * rhs;” would create an expression `exp` that represents the object pointed to by the pointer value `rhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Pointer dereferencing is only valid when the operand is a pointer. Any other operand data type is invalid. When the operand is a pointer it has the usual meaning associated with dereferencing pointers and the data type of the result of executing the expression is the data type of the pointee.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the dereferencing of a pointer operand.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of the operand is inappropriate

#include <ProbeExp.h>

ProbeExp operator *=(const ProbeExp &rhs)
```

#### Parameters

- `rhs` right operand

#### Description

This function creates a probe expression that represents the multiplication of two operands, and its subsequent storage of the result into the invoking object. The left operand represents the invoking object, while the argument `rhs` represents the right operand. The left operand must be an object in memory, while the right operand may be an object in memory or an expression that evaluates to a value. For example, “`ProbeExp exp = lhs *= rhs;`” would create an expression `exp` that represents the multiplication of two values, `lhs` and `rhs`, and its assignment to `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Multiplication is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

#### Return value

Probe expression representing the multiplication of two operands and assignment of the result.

#### Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of one or both operands is inappropriate

#### See Also
9.24 operator /

Synopsis

```c
#include <ProbeExp.h>
ProbeExp operator / (const ProbeExp &rhs)
```

Parameters

- rhs: right operand

Description

This function creates a probe expression that represents the division of two operands. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, ```ProbeExp exp = lhs / rhs;``` would create an expression `exp` that represents the division of `rhs` by `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Division is only valid when both operands are integers, and the divisor is non-zero. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the division of two operands.

Exceptions

- ASC_insufficient_memory: insufficient memory to create a new node
- ASC_invalid_expression: data type of one or both operands is inappropriate

*Synopsis*

```
#include <ProbesExp.h>
ProbesExp operator % (const ProbesExp &rhs)
```

*Parameters*

- `rhs` right operand

*Description*

This function creates a probe expression that represents the division of two operands, where the remainder rather than the dividend is returned. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, "ProbesExp exp = lhs % rhs;" would create an expression `exp` that represents the division of `rhs` by `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Division is only valid when both operands are integers, and the divisor is non-zero. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

*Return value*

ProbesExp expression representing the remainder of the division of two operands.

*Exceptions*

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of one or both operands is inappropriate

*See Also*
9.27 operator %=

Synopsis

```c
#include <ProbeExp.h>
ProbeExp operator %= (const ProbeExp &rhs)
```

Parameters

- `rhs` right operand

Description

This function creates a probe expression that represents the division of two operands, where the remainder rather than the dividend is returned, and its subsequent storage of the result into the invoking object. The left operand represents the invoking object, while the argument `rhs` represents the right operand. The left operand must be an object in memory, while the right operand may be an object in memory or an expression that evaluates to a value. For example, “`ProbeExp exp = lhs %= rhs;`” would create an expression `exp` that represents the division of two values, `lhs` and `rhs`, and its assignment to `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Division is only valid when both operands are integers, and the divisor is non-zero. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with computer arithmetic of signed integers and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the division of two operands and assignment of the remainder.

Exceptions

- **ASC_insufficient_memory** insufficient memory to create a new node
- **ASC_invalid_expression** data type of one or both operands is inappropriate

See Also
9.28 operator =

Synopsis

#include <ProbeExp.h>

ProbeExp &operator = (const ProbeExp &rhs)

Parameters

rhs right operand

Description

This function does not create a node in a probe expression tree. Rather, it performs a local assignment on the client, of the value in the right operand to the object represented by the left operand. For example, “ProbeExp lhs; lhs = rhs;” would assign the value contained in rhs to the variable lhs. Notice that the above example is different from “ProbeExp lhs = rhs;” in that the first example invokes the assignment operator, “operator =”, while the second example invokes the copy constructor. But though different functions are called the end result is the same, that is, the probe expression represented by the right operand is assigned to the object represented by the left operand.

Return value

A reference to the invoking object (i.e., the left operand).

See Also
9.29 operator ==

Synopsis

```c
#include <ProbeExp.h>

ProbeExp operator == (const ProbeExp &rhs)
```

Parameters

- rhs  
  right operand

Description

This function creates a probe expression that represents a comparison for equality of two operands, where 1 is returned if they are equal, and 0 is returned if they are not. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, ```ProbeExp exp = lhs == rhs;``` would create an expression `exp` that represents a comparison for equality of `rhs` and `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Comparison for equality is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with comparison of signed integers and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the comparison of two operands for equality.

Exceptions

- ASC_insufficient_memory  
  insufficient memory to create a new node
- ASC_invalid_expression  
  data type of one or both operands is not an integer

See Also
**9.30 operator !**

*Synopsis*

```c
#include <ProbeExp.h>

ProbeExp operator ! (void)
```

*Description*

This function creates a probe expression that represents the logical negation of an operand, where 0 is returned if the operand is a non-zero value, and 1 is returned if the operand is 0. The right operand represents the invoking object. The operand may be an object in memory or an expression that evaluates to a value. For example, “ProbeExp exp = ! rhs;” would create an expression `exp` that represents the negation of `rhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Logical negation is only valid when the operand is a signed integer. Any other operand data type is invalid. When the operand is an integer it has the usual meaning associated with computer logic and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

*Return value*

Probe expression representing the negation of an operand.

*Exceptions*

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of the operand is inappropriate

*See Also*
9.31 operator !=

Synopsis

```c
#include <ProbeExp.h>
ProbeExp operator != (const ProbeExp &rhs)
```

Parameters

- `rhs` right operand

Description

This function creates a probe expression that represents a comparison for inequality of two operands, where 0 is returned if they are equal, and 1 is returned if they are not. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, "```c
ProbeExp exp = lhs != rhs;
```" would create an expression `exp` that represents a comparison for equality of `rhs` and `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Comparison for equality is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with comparison of signed integers and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the comparison of two operands for inequality.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of one or both operands is not an integer

See Also
9.32 operator <

Synopsis

    #include <ProbeExp.h>

    ProbeExp operator < (const ProbeExp &rhs)

Parameters

    rhs                   right operand

Description

This function creates a probe expression that represents a comparison of two operands, where 1 is returned if the left operand is less than the right operand, and 0 is returned otherwise. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, "ProbeExp exp = lhs < rhs;" would create an expression `exp` that represents a comparison of `rhs` and `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Comparison is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with relational operators and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

    Probe expression representing the comparison of two operands for relative size.

Exceptions

    ASC_insufficient_memory   insufficient memory to create a new node
    ASC_invalid_espression    data type of one or both operands is not an integer

See Also
9.33 operator <=

Synopsis

    #include <ProbeExp.h>
    ProbeExp operator <= (const ProbeExp &rhs)

Parameters

    rhs                    right operand

Description

This function creates a probe expression that represents a comparison of two operands, where
1 is returned if the left is less than or equal to the right, and 0 is returned otherwise. The invoking object represents the left operand, while the argument rhs represents the right operand.
The operands may be objects in memory or expressions that evaluate to values. For example,  
“ProbeExp exp = lhs <= rhs;” would create an expression exp that represents a comparison of rhs and lhs. The expression exp could then be used as a sub-expression in an assignment or other type of statement or expression.
Comparison is only valid when both operands are integers. Any other combination of operand
data types is invalid. When both operands are integers it has the usual meaning associated with
relational operators and the data type of the result of executing the expression is an integer.
This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the comparison of two operands for relative size.

Exceptions

    ASC_insufficient_memory   insufficient memory to create a new node
    ASC_invalid_expression    data type of one or both operands is not an integer

See Also
9.34 operator <<

Synopsis

```cpp
#include <ProbeExp.h>

ProbeExp operator << (const ProbeExp &rhs)
```

Parameters

- `rhs` right operand

Description

This function creates a probe expression that represents a bit-wise left shift of the left operand. When the right operand is positive, the value returned is the left operand shifted that many places to the left. When the right operand is zero, the value returned is the value of the left operand. When the right operand is negative, the value returned is the left operand shifted that many places to the right. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, ```ProbeExp exp = lhs << rhs;``` would create an expression `exp` that represents a left shift of `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Left shift is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with bit-wise shift operators and the data type of the result of executing the expression is an integer. This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the left shift of the left operator.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of one or both operands is not an integer

See Also
9.35 operator <<=

Synopsis

```cpp
#include <ProbeExp.h>
ProbeExp operator <<= (const ProbeExp &rhs)
```

Parameters

- rhs: right operand

Description

This function creates a probe expression that represents a bit-wise left shift of the left operand. When the right operand is positive, the value returned is left operand shifted that many places to the left. When the right operand is zero, the value returned is the value of the left operand. When the right operand is negative, the value returned is the left operand shifted that many places to the right. The result is subsequently stored into the invoking object. The left operand represents the invoking object, while the argument `rhs` represents the right operand. The left operand must be an object in memory, while the right operand may be an object in memory or an expression that evaluates to a value. For example, “```cpp
ProbeExp exp = lhs <<= rhs;
```” would create an expression `exp` that represents the left shift of `lhs` by `rhs`, and its assignment to `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Shift operations are only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with bit-wise shift operations and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing a left bit-wise shift and assignment of the result.

Exceptions

- `ASC_insufficient_memory`: insufficient memory to create a new node
- `ASC_invalid_expression`: data type of one or both operands is inappropriate

See Also

9.36 operator >

Synopsis

```cpp
#include <ProbeExp.h>

ProbeExp operator > (const ProbeExp &rhs)
```

Parameters

- `rhs` - right operand

Description

This function creates a probe expression that represents a comparison of two operands, where 1 is returned if the left operand is greater than the right operand, and 0 is returned otherwise. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, `ProbeExp exp = lhs > rhs;` would create an expression `exp` that represents a comparison of `rhs` and `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Comparison is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with relational operators and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the comparison of two operands for relative size.

Exceptions

- `ASC_insufficient_memory` - insufficient memory to create a new node
- `ASC_invalid_expression` - data type of one or both operands is not an integer

See Also
9.37 operator >=

Synopsis

```c
#include <ProbeExp.h>

ProbeExp operator >= (const ProbeExp &rhs)
```

Parameters

- `rhs` right operand

Description

This function creates a probe expression that represents a comparison of two operands, where 1 is returned if the left is greater than or equal to the right, and 0 is returned otherwise. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, “`ProbeExp exp = lhs >= rhs;`” would create an expression `exp` that represents a comparison of `rhs` and `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Comparison is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with relational operators and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the comparison of two operands for relative size.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_espression` data type of one or both operands is not an integer

See Also
9.38 operator >>

Synopsis

    #include <ProbeExp.h>

    ProbeExp operator >> (const ProbeExp &rhs)

Parameters

    rhs : right operand

Description

This function creates a probe expression that represents a bit-wise right shift of the left operand. When the right operand is positive, the value returned is the left operand shifted that many places to the right. When the right operand is zero, the value returned is the value of the left operand. When the right operand is negative, the value returned is the left operand shifted that many places to the left. The invoking object represents the left operand, while the argument rhs represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, “ProbeExp exp = lhs >> rhs;” would create an expression exp that represents a left shift of lhs. The expression exp could then be used as a sub-expression in an assignment or other type of statement or expression.

Right shift is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with bit-wise shift operators and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

    Probe expression representing the right shift of the left operator.

Exceptions

    ASC_insufficient_memory : insufficient memory to create a new node
    ASC_invalid_expression : data type of one or both operands is not an integer

See Also
9.39 operator >>=

Synopsis

```
#include <ProbeExp.h>

ProbeExp operator >>= (const ProbeExp &rhs)
```

Parameters

- `rhs` right operand

Description

This function creates a probe expression that represents a bit-wise right shift of the left operand. When the right operand is positive, the value returned is left operand shifted that many places to the right. When the right operand is zero, the value returned is the value of the left operand. When the right operand is negative, the value returned is the left operand shifted that many places to the left. The result is subsequently stored into the invoking object. The left operand represents the invoking object, while the argument `rhs` represents the right operand. The left operand must be an object in memory, while the right operand may be an object in memory or an expression that evaluates to a value. For example, "`ProbeExp exp = lhs >>= rhs;`" would create an expression `exp` that represents the right shift of `lhs` by `rhs`, and its assignment to `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Shift operations are only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with bit-wise shift operations and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing a right bit-wise shift and assignment of the result.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of one or both operands is inappropriate

See Also
9.40 operator & (binary)

Synopsis

```c
#include <ProbeExp.h>

ProbeExp operator & (const ProbeExp &rhs)
```

Parameters

- `rhs` right operand

Description

This function creates a probe expression that represents a bit-wise `AND` of the left and right operands. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, “`ProbeExp exp = lhs & rhs;`” would create an expression `exp` that represents a bit-wise `AND` of `lhs` and `rhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Bit-wise `AND` is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with bit-wise `AND` operators and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the bit-wise `AND` of the left and right operands.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of one or both operands is not an integer

See Also
9.41 operator & (unary)

Synopsis

```c
#include <ProbeExp.h>
ProbeExp *operator & (void)
```

Description

This function does not create a node in a probe expression tree. Rather, it computes and returns the address of the invoking object on the client. For example, the probe expression “ProbeExp *ptr = &obj;” would store a pointer to the object obj in the pointer ptr. It is necessary that the function work in this manner and not create an expression tree, to allow C++ to pass objects by reference.

Return value

A pointer to the invoking object on the client.

See Also
9.42 `operator &=`

**Synopsis**

```c
#include <ProbeExp.h>
ProbeExp operator &= (const ProbeExp &rhs)
```

**Parameters**

- `rhs` right operand

**Description**

This function creates a probe expression that represents a bit-wise `AND` of the operands. The result is subsequently stored into the invoking object. The left operand represents the invoking object, while the argument `rhs` represents the right operand. The left operand must be an object in memory, while the right operand may be an object in memory or an expression that evaluates to a value. For example, “`ProbeExp exp = lhs &= rhs;`” would create an expression `exp` that represents the bit-wise `AND` of `lhs` and `rhs`, and its assignment to `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Bit-wise operations are only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with bit-wise `AND` operations and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

**Return value**

Probe expression representing a bit-wise `AND` and assignment of the result.

**Exceptions**

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of one or both operands is inappropriate

**See Also**
9.43 operator &&

Synopsis

```cpp
#include <ProbeExp.h>

ProbeExp operator && (const ProbeExp &rhs)
```

Parameters

- **rhs**: right operand

Description

This function creates a probe expression that represents a logical AND of two operands, where 1 is returned if both operands are non-zero, and 0 is returned if one or more are not. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, "ProbeExp exp = lhs && rhs;" would create an expression `exp` that represents a logical AND of `rhs` and `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Logical AND is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with logical expressions and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the logical AND of two operands.

Exceptions

- `ASC_insufficient_memory`: insufficient memory to create a new node
- `ASC_invalid_expression`: data type of one or both operands is not an integer

See Also
9.44 operator

**Synopsis**

```c
#include <ProbeExp.h>

ProbeExp operator | (const ProbeExp &rhs)
```

**Parameters**

- `rhs` - right operand

**Description**

This function creates a probe expression that represents a bit-wise `OR` of the left and right operands. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, `ProbeExp exp = lhs | rhs;` would create an expression `exp` that represents a bit-wise `OR` of `lhs` and `rhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Bit-wise `OR` is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with bit-wise `OR` operators and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

**Return value**

Probe expression representing the bit-wise `OR` of the left and right operands.

**Exceptions**

- `ASC_insufficient_memory` - insufficient memory to create a new node
- `ASC_invalid_espression` - data type of one or both operands is not an integer

**See Also**
9.45 operator |=

Synopsis

```
#include <ProbeExp.h>

ProbeExp operator |= (const ProbeExp &rhs)
```

Parameters

- `rhs` right operand

Description

This function creates a probe expression that represents a bit-wise OR of the operands. The result is subsequently stored into the invoking object. The left operand represents the invoking object, while the argument `rhs` represents the right operand. The left operand must be an object in memory, while the right operand may be an object in memory or an expression that evaluates to a value. For example, “ProbeExp exp = lhs |= rhs;” would create an expression `exp` that represents the bit-wise OR of `lhs` and `rhs`, and its assignment to `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Bit-wise operations are only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with bit-wise OR operations and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing a bit-wise OR and assignment of the result.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_espression` data type of one or both operands is inappropriate

See Also
9.46 operator ||

Synopsis

```
#include <ProbeExp.h>

ProbeExp operator || (const ProbeExp &rhs)
```

Parameters

- **rhs**: right operand

Description

This function creates a probe expression that represents a logical OR of two operands, where 1 is returned at least one operand is non-zero, and 0 is returned if both are zero. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, "ProbeExp exp = lhs || rhs;" would create an expression `exp` that represents a logical OR of `rhs` and `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Logical OR is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with logical expressions and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

- Probe expression representing the logical OR of two operands.

Exceptions

- `ASC_insufficient_memory`: insufficient memory to create a new node
- `ASC_invalid_expression`: data type of one or both operands is not an integer

See Also
9.47 operator ^

Synopsis

```cpp
#include <ProbeExp.h>

ProbeExp operator ^ (const ProbeExp &rhs)
```

Parameters

- `rhs` right operand

Description

This function creates a probe expression that represents a bit-wise exclusive-OR of the left and right operands. The invoking object represents the left operand, while the argument `rhs` represents the right operand. The operands may be objects in memory or expressions that evaluate to values. For example, “`ProbeExp exp = lhs ^ rhs;`” would create an expression `exp` that represents a bit-wise exclusive-OR of `lhs` and `rhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Bit-wise exclusive-OR is only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with bit-wise exclusive-OR operators and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the bit-wise exclusive-OR of the left and right operands.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of one or both operands is not an integer

See Also
**9.48 operator ^=**

*Synopsis*

```cpp
#include <ProbeExp.h>

ProbeExp operator ^= (const ProbeExp &rhs)
```

*Parameters*

- `rhs` : right operand

*Description*

This function creates a probe expression that represents a bit-wise `exclusive-OR` of the operands. The result is subsequently stored into the invoking object. The left operand represents the invoking object, while the argument `rhs` represents the right operand. The left operand must be an object in memory, while the right operand may be an object in memory or an expression that evaluates to a value. For example, `ProbeExp exp = lhs ^= rhs;` would create an expression `exp` that represents the bit-wise `exclusive-OR` of `lhs` and `rhs`, and its assignment to `lhs`. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Bit-wise operations are only valid when both operands are integers. Any other combination of operand data types is invalid. When both operands are integers it has the usual meaning associated with bit-wise `exclusive-OR` operations and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

*Return value*

Probes expression representing a bit-wise `exclusive-OR` and assignment of the result.

*Exceptions*

- `ASC_insufficient_memory` : insufficient memory to create a new node
- `ASC_invalid_expression` : data type of one or both operands is inappropriate

*See Also*
9.49 operator ~

Synopsis

```cpp
#include <ProbeExp.h>

ProbeExp operator ~ (void)
```

Description

This function creates a probe expression that represents the bit-wise inversion of an operand. The right operand represents the invoking object. The operand may be an object in memory or an expression that evaluates to a value. For example, “ProbeExp exp = ~ rhs;” would create an expression exp that represents the inversion of rhs. The expression exp could then be used as a sub-expression in an assignment or other type of statement or expression.

Bit-wise inversion is only valid when the operand is a signed integer. Any other operand data type is invalid. When the operand is an integer it has the usual meaning associated with computer logic and the data type of the result of executing the expression is an integer.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the bit-wise inversion of an operand.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_espression` data type of the operand is inappropriate

See Also
9.50 operator []

Synopsis

```c
#include <ProbeExp.h>
ProbeExp operator [] (int index)
```

Parameters

- `rhs` right operand

Description

This function creates a probe expression that represents the indexing and dereference of a pointer operand. The invoking object represents the left (pointer) operand, while the argument `rhs` represents the right (index) operand. The operands may be objects in memory or expressions that evaluate to values. For example, “`ProbeExp exp = lhs [ rhs ];`” would create an expression `exp` that represents adding `rhs` to `lhs` and dereferencing the result. The expression `exp` could then be used as a sub-expression in an assignment or other type of statement or expression.

Index and dereference is only valid when the left operand is a pointer and the right operand is an integer. Any other combination of operand data types is invalid. When both operands are of appropriate data types it has the usual meaning associated with index and dereferencing and the data type of the result of executing the expression matches the pointee.

This expression may be executed on the application process only after it has been installed and activated.

Return value

Probe expression representing the index and dereference of the left and right operands.

Exceptions

- `ASC_insufficient_memory` insufficient memory to create a new node
- `ASC_invalid_expression` data type of one or both operands is inappropriate

See Also
### 9.51 sequence

**Synopsis**

```c
#include <ProbeExp.h>

ProbeExp sequence(const ProbeExp &second)
```

**Parameters**

- `second` second expression in the sequence

**Description**

This function creates a probe expression that represents the joining of two probe expressions into a sequence. The invoking object represents the first expression in the sequence to be executed, while the argument `second` represents the second expression to be executed. The operands may be objects in memory or expressions that evaluate to values. For example, “`ProbeExp exp = first.sequence(second);`” would create an expression `exp` that represents the execution of `first` followed by `second`. The expression `exp` could then be used as a sub-expression in a conditional expression, a sequence, or other type of statement or expression.

This expression may be executed on the application process only after it has been installed and activated.

**Return value**

Probe expression representing the sequencing of two expressions.

**Exceptions**

- `ASC_insufficient_memory` insufficient memory to create a new node

**See Also**
9.52 value *

Synopsis

```c
int8_t value_int8(void) const
int16_t value_int16(void) const
int32_t value_int32(void) const
int64_t value_int64(void) const
uint8_t value_uint8(void) const
uint16_t value_uint16(void) const
uint32_t value_uint32(void) const
uint64_t value_uint64(void) const

float64_t value_float64(void) const
const char *value_text(void) const
ProbeExp value_left(void) const
ProbeExp value_right(void) const
ProbeExp value_center(void) const
```

Description

Returns the value contained in the node.

Return value

The value, of the indicated type, contained within the node.

Exceptions

- `ASC_invalid_value_ref` node does not contain a value of the indicated type

See Also
10.0 class ProbeHandle

10.1 Constructors

Synopsis

```cpp
#include <ProbeHandle.h>
ProbeHandle(void)
ProbeHandle(const ProbeHandle &copy)
```

Parameters

copy object to be duplicated in the copy constructor

Description

Two constructors are provided with this class -- a default constructor and a copy constructor. The default constructor is able to create storage, marked initially as containing invalid probe handles, that may later be assigned or initialized through a probe installation.

The copy constructor performs a similar operation to assignment, but operates on an uninitialized object.

Exceptions

ASC_insufficient_memory insufficient memory to create a new node

See Also
10.2 get_expression

Synopsis

```
#include <ProbeHandle.h>

ProbeExp get_expression(void)
```

Description

This function returns the original probe expression installed in the application process. Note that the expression returned is the original and not a copy, so alterations to the original after it has been installed will be reflected in the expression returned by this function.

Return value

Original probe expression installed in the application process.

See Also
10.3 get_point

Synopsis

```c
#include <ProbeHandle.h>

InstPoint get_point(void)
```

Description

This function returns the original instrumentation point where the probe expression was installed in the application process.

Return value

Instrumentation point where the probe expression was installed in the application process.

See Also
10.4 operator =

Synopsis

#include <ProbeHandle.h>

ProbeHandle &operator = (const ProbeHandle &copy)

Parameters

copy object to be duplicated in the assignment operator

Description

This function copies the argument over the top of the invoking object.

Return value

Reference to the invoking object.

See Also
#class ProbeModule

##11.0 class ProbeModule

###11.1 Constructors

**Synopsis**

```cpp
#include <ProbeModule.h>
ProbeModule(void)
ProbeModule(const ProbeModule &copy)
ProbeModule(const char *filename)
```

**Parameters**

- `copy`: probe module that will be duplicated in a copy constructor
- `filename`: name and path of an object file (*.o) that contains functions and data to be loaded into the application process

**Description**

The default constructor creates an empty probe module structure, in other words, a structure that contains no objects. The default constructor is invoked when uninitialized probe modules are created, such as in arrays. Objects within the array can be overwritten using an assignment operator (`operator =`).

The copy constructor is used to transfer the contents of an initialized object (the `copy` parameter) to an uninitialized object.

The standard constructor reads the object file (*.o) that contains functions and data to be loaded into the application process. It reads the file to determine what data and functions are available and the data type signature of each.

**Exceptions**

- `ASC_insufficient_memory`: not enough memory to create a new node

**See Also**
11.2 get_count

Synopsis

```
#include <ProbeModule.h>

int get_count(void)
```

Description

This function returns the number of data objects and functions in the module. If the module was initialized by a default constructor or its value was copied from a default constructor, this function returns 0.

Return value

Number of data objects and functions in the module, or 0 if the module was initialized by a default constructor.

See Also
11.3 get_object

Synopsis

```c
#include <ProbeModule.h>

ProbeExp get_object(int index)
```

Parameters

- `index`: index of the desired function or data object, equal to or greater than zero, and less than `get_count()`.

Description

This function returns a probe expression that represents the desired data or function. If the index is out of range, that is, if it is less than zero or equal to or greater than `get_count()`, it returns an “undefined” probe expression.

Return value

A probe expression that represents the desired data or function, or “undefined” if the index is out of range.

See Also
11.4 operator =

Synopsis

```
#include <ProbeModule.h>

ProbeModule &operator = (const ProbeModule &rhs)
```

Parameters

- `rhs` : right operand

Description

This function assigns the value of the right operand to the invoking object. The left operand is the invoking object. For example, “```ProbeModule rhs, lhs; ... lhs = rhs;```” assigns the value of `rhs` to `lhs`. Then one can be used interchangeably with the other.

Return value

A reference to the invoking object (i.e., the left operand).

See Also
11.5 operator ==

Synopsis

```
#include <ProbeModule.h>
int operator == (const ProbeModule &compare)
```

Parameters

- `compare` probe module to be compared against the invoking object

Description

This function compares two probe modules for equivalence. If the two objects represent the same probe module or two modules constructed with the same parameters, this function returns 1. Otherwise it returns 0.

Return value

This function returns 1 if the two objects are equivalent, 0 otherwise.

See Also
11.6 operator !=

Synopsis

```c
#include <ProbeModule.h>

int operator != (const ProbeModule &compare)
```

Parameters

- `compare` probe module to be compared against the invoking object

Description

This function compares two probe modules for equivalence. If the two objects represent the same probe module or two modules constructed with the same parameters, this function returns 0. Otherwise it returns 1.

Return value

This function returns 0 if the two objects are equivalent, 1 otherwise.

See Also
12.0 class ProbeType

12.1 Supporting Data Types

12.1.1 DataExpNodeType

Synopsis

```c
enum DataExpNodeType {
    DEN_array_type, // array type decl -- x[y]
    DEN_class_type, //
    DEN_enum_type, // enum type decl -- enum x {y}
    DEN_float32_type, // float32 type decl
    DEN_float64_type, // float64 type decl
    DEN_function_type, //
    DEN_int16_type, // int16 type declaration
    DEN_int32_type, // int32 type declaration
    DEN_int64_type, // int64 type declaration
    DEN_int8_type, // int8 type declaration
    DEN_pointer_type, // pointer type exp -- * x
    DEN_reference_type, // reference type -- & x
    DEN_struct_type, //
    DEN_uint16_type, // uint16 type declaration
    DEN_uint32_type, // uint32 type declaration
    DEN_uint64_type, // uint64 type declaration
    DEN_uint8_type, // uint8 type declaration
    DEN_union_type, //
    DEN_user_type, // user defined type name
    DEN_void_type, // void data type
    DEN_undef_node, // undefined ENT node
    DEN_LAST_TYPE
}
```
Description

Values of type ProbeType are expression trees that represent the data type of an object within an application process. The object may be an application object, that is, it may be a part of the application program, or it may be a probe object, that is, an object allocated and used by the instrumentation system. This data structure reflects all of the possible enumeration values used by the expression tree to represent the data type of the object. It is a combination of the enumeration value of each node, and the placement of nodes within the tree, that describes the data type of the object.

See Also
12.2 Constructors

Synopsis

    #include <ProbeType.h>
    ProbeType(void)

Description

The default constructor creates an object with undefined data type.

See Also
12.3 child

Synopsis

```
#include <ProbeType.h>

ProbeType child(int index) const
```

Parameters

- `index`: index of the sub-type, which must be greater than or equal to zero, and less than `child_count()`

Description

This function returns the sub-type of a data type. For example, if the invoking object represents a pointer to an object, `child(0)` returns the data type of the pointee. For data types representing functions, `child(0)` returns the data type of the return value, `child(1)` returns the data type of the first argument, if any, `child(2)` returns the data type of the second argument, if any, etc.

Return value

The data type of the indicated sub-type.

See Also
12.4 child_count

Synopsis

```c
#include <ProbeType.h>

int child_count(void) const
```

Description

This function returns the number of sub-types associated with this data type. Undefined data types, created by the default constructor, return zero. Children can be the data type of a pointer, function return types, function argument data types, etc.

Return value

Number of child sub-types associated with this data type.

See Also
### 12.5 function_type

**Synopsis**

```c
#include <ProbeType.h>

ProbeType function_type(
    ProbeType return_type,
    int count,
    ProbeType *args)
```

**Parameters**

- `return_type` data type of the function return value
- `count` number of function arguments
- `args` array of argument data types

**Description**

This function creates a data type that represents the prototype or type signature of a function.

**Return value**

Data type that represents the prototype of a function.

**See Also**
12.6 get_node_type

Synopsis

#include <ProbeType.h>

DataExpNodeType get_node_type(void) const

Description

This function returns the enumeration value, or node type, of this node in the data type expression tree.

Return value

Node type of this node in the data type expression tree.

See Also
### 12.7 int32_type

**Synopsis**

```c
#include <ProbeType.h>

ProbeType int32_type(void)
```

**Description**

This function creates an object that represents a 32-bit integer data type.

**Return value**

Data type that represents a 32-bit integer.

**See Also**
12.8 operator =

Synopsis

#include <ProbeType.h>

ProbeType &operator = (const ProbeType &copy)

Parameters

  copy          probe type to be duplicated

Description

  This function transfers the contents of the copy parameter to the object.

Return value

  Reference to the object.

See Also
12.9 operator ==

Synopsis

    #include <ProbeType.h>
    int operator == (const ProbeType &compare)

Parameters

    compare            probe type to be compared

Description

    This function compares two probe types for equivalence. If the two data types are equivalent, this function returns 1. Otherwise it returns 0.

Return value

    This function returns 1 if the two data types are equivalent, 0 otherwise.

See Also
### 12.10 operator !=

**Synopsis**

```c
#include <ProbeType.h>
int operator != (const ProbeType &compare)
```

**Parameters**

- `compare` : probe type to be compared

**Description**

This function compares two probe types for equivalence. If the two data types are equivalent, this function returns 0. Otherwise it returns 1.

**Return value**

This function returns 0 if the two types are equivalent, 1 otherwise.

**See Also**
**12.11 pointer_type**

*Synopsis*

```cpp
#include <ProbeType.h>

ProbeType pointer_type(const ProbeType &pointee)
```

*Parameters*

`pointee` data type the pointer will point to

*Description*

This function creates an object that represents the data type of a pointer to a pointee.

*Return value*

Data type that represents a pointer to a pointee.

*See Also*
12.12 stack

Synopsis

```
#include <ProbeType.h>

ProbeExp stack(void *init_val)
```

Parameters

- `init_val` initial value to be given to the stack reference when the reference is allocated on the stack

Description

This function converts a data type into a probe expression that represents a stack reference.

Return value

A probe expression that represents a stack reference.

See Also
12.13 unspecified_type

Synopsis

```c
#include <ProbeType.h>

ProbeType unspecified_type(int size)
```

Parameters

- `size`: number of bytes objects of this data type require

Description

This function creates an object that represents an unspecified data type. The data type must be given a size greater than zero.

Return value

Data type that represents an unspecified data type.

See Also
13.0 class Process

13.1 Constructors

Synopsis

```cpp
#include <Process.h>
Process(void)
Process(const Process &copy)
Process(const char *host_name, int task_pid, int task_num = 0)
```

Parameters

- `copy` object to be copied into the new Process object
- `host_name` host name or IP address where the process is located. If 0 then the process is considered local
- `task_pid` process id for the task
- `task_num` task number for the given process

Description

The default constructor creates a Process object in an “unused” state. Specifically, the task number and process ID are both -1, and the host name is 0.

The copy constructor uses the values contained in the `copy` argument to initialize the new (constructed) object. No attempt is made to connect to the process represented by the `copy` argument, whether or not it is already connected.

The standard constructor uses the arguments provided to initialize the object. No attempt is made to connect to the process. `Task_num` is a value that is used only by queries on the client and does not affect the connection in any way.

Exceptions

Exceptions that could be raised as a result of calling this function are unknown at this time.

See Also

- `connect`, `bconnect`, `bdisconnect`, `disconnect`, `remove_process`. 
13.2 activate_probe

Synopsis

#include <Process.h>
AisStatus activate_probe(
  short count,
  ProbeHandle *phandle,
  GCBFuncType ack_cb_fp,
  GCBTagType ack_cb_tag)

Parameters

count  number of probe expressions in the list to be activated
phandle  array of probe handles, one for each probe expression to be activated
ack_cb_fp  acknowledgement callback function to be invoked when all probe expressions in the array have been activated (or activation fails)
ack_cb_tag  tag to be used with the acknowledgement callback function

Description

This function activates a list of probes that have been installed within a process. The activation is atomic in the sense that all probes are activated or all probes fail to be activated for the process.

Phandle is an input array generated by an install_probe or binstall_probe call. It is supplied by the caller and must contain at least count elements. The i\textsuperscript{th} element of the array is a handle, or identifier, that identifies the i\textsuperscript{th} probe expression.

To activate a set of probes the process must have been previously connected, and the probes must have been previously installed in that process.

Note that the function submits the request to activate the probes and returns immediately. The acknowledgement callback function receives notification of the success or failure of the activation.

Return value

The return value indicates whether the request for activation was successfully submitted, but indicates nothing about whether the request itself was successfully executed.

ASC_success  all activations were successfully submitted
ASC_???
Callback Data

The callback function is invoked once for each process for which a probe activation is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

- ASC_success probes were successfully activated on this process
- ASC_operation_failed attempt to activate these probes in this process failed

See Also

bactivate_probe, bconnect, bdisconnect, bprobe_deactivate, bprobe_install, class Process, connect, disconnect, 
GCBFuncType, probe_deactivate, probe_install, ProbeHandle::activate
13.3 add_phase

Synopsis

```
#include <Process.h>

AisStatus add_phase(
    Phase ps,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- **ps**: data structure local to the client containing the characteristics of the phase to be created
- **ack_cb_fp**: acknowledgement callback function to be invoked each time the phase has been created within a process
- **ack_cb_tag**: tag to be used with the acknowledgement callback function

Description

This function adds a new phase structure to the process. A process *must* be connected in order to add a new phase.

Return value

The return value indicates whether the request for phase addition was successfully submitted, but indicates nothing about whether the request itself was successfully executed.

- **ASC_success**: activation request was successfully submitted
- **ASC_???:**

Callback Data

The callback function is invoked exactly once for this process. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- **ASC_success**: probes were successfully activated on this process
- **ASC_operation_failed**: attempt to activate these probes on this process failed

Callback Data

The callback function is invoked once for each process for which a phase addition is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:
ASC_success phase was successfully added to this process
ASC_operation_failed attempt to add a phase to this process failed

See Also
badd_phase, bconnect, bdisconnect, class GenCallBack, class ProbeModule, class Process, connect, disconnect, GCBFuncType, GCBTagType, Process::malloc, Process::free.
### 13.4 attach

**Synopsis**

```c
#include <Process.h>

AisStatus attach(GCBFuncType fp, GCBTagType tag)
```

**Parameters**

- `fp` callback function to be invoked with a successful or failed attachment to this process.
- `tag` callback tag to be used as a parameter to the callback when the callback function is invoked.

**Description**

Attach to this process. When multiple tools are connected to a process or application, only one tool can be attached at a time. Attaching to a process allows the tool to control the execution directly, setting break points, starting and stopping execution, etc. Processes must be first connected before they can be attached.

Note that the function submits the request to attach to a process and returns immediately. The callback function receives notification of the success or failure of attachment.

**Return value**

The return value for `attach` indicates whether the request was successfully submitted, but indicates nothing about whether the request itself was successfully executed.

**Callback Data**

The callback function is invoked once for each process for which an attach is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` process was successfully attached
- `ASC_operation_failed` attempt to attach to this process failed

**See Also**

- `connect`, `bconnect`, `bdisconnect`, `detach`, `disconnect`
### 13.5 bactivate_probe

**Synopsis**

```c
#include <Process.h>

AisStatus bactivate_probe(short count, ProbeHandle *phandle)
```

**Parameters**

- `count`: number of probe expressions in the list to be activated
- `phandle`: array of probe handles, one for each probe expression to be activated

**Description**

This function activates a list of probes that have been installed within a process. The activation is atomic in the sense that all probes are activated or all probes fail to be activated for any given process.

`Phandle` is an input array generated by an `install_probe` or `binstall_probe` call. It is supplied by the caller and must contain at least `count` elements. The `i`<sup>th</sup> element of the array is a handle, or identifier, that identifies the `i`<sup>th</sup> probe expression.

To activate a set of probes the process must have been previously connected, and the probes must have been previously installed in the process.

Note that the function submits the request to activate the probes and waits until the request has completed.

**Return value**

The return value indicates whether the request for activation was successfully executed.

- `ASC_success`: all activations were successfully completed
- `ASC_operation_failed`: all activations failed

**Exceptions**

Exceptions that could be raised as a result of calling this function are unknown at this time.

AisStatus `???`

**See Also**

activate_probe, bconnect, bdisconnect, bprobe_deactivate, bprobe_install, connect, disconnect, probe_deactivate, probe_install.
13.6 badd_phase

Synopsis

```c
#include <Process.h>
AisStatus badd_phase(Phase ps)
```

Parameters

- `ps`: data structure local to the client containing the characteristics of the phase to be created

Description

This function adds a new phase structure to a connected process. A process must be connected in order to add a new phase.

Note that the function submits a request to add the phase and waits until the request has completed. The return value indicates whether the request was successfully executed.

Return value

The return value indicates whether the request for phase addition was successfully executed.

- `ASC_success`: phase was successfully added to the process
- `ASC_operation_failed`: phase addition failed

See Also

- `add_phase`, `bconnect`, `bdisconnect`, `class ProbeModule`, `connect`, `disconnect`, `Process::malloc`, `Process::free`
### 13.7 battach

**Synopsis**

```c
#include <Process.h>
AisStatus battach(void)
```

**Description**

Attach to a process. When multiple tools are connected to a process or application, only one tool can be attached at a time. Attaching to a process or application allows the tool to control the execution directly, setting break points, starting and stopping execution, *etc.*

Note that `battach` does not return control to the caller until the attachment has either succeeded or failed. The return value indicates whether the attachment succeeded or failed.

**Return value**

The return value for `battach` indicates whether the attachment was successfully established.

- **ASC_success**  
  process was successfully attached as expected.
- **ASC_operation_failed**  
  the process failed to attach

**See Also**
13.8 bconnect

Synopsis

```
#include <Process.h>
AisStatus bconnect(void)
```

Description

Connect to a process. Connection to a process establishes a communication channel to the CPU where the process resides and creates the environment within that process that allows the client to insert and remove instrumentation, etc.

Note that `bconnect` does not return control to the caller until the connection has either succeeded or failed. The return value indicates whether the connection succeeded or failed.

Return value

The return value for `bconnect` indicates whether the connection was successfully established.

- `ASC_success` connection was successfully established as expected.
- `ASC_operation_failed` connection failed to be established.

See Also
13.9 bcreate

Synopsis

```
#include <Process.h>
AisStatus bcreate(
    const char *host,
    const char *path,
    char *const args[],
    char *const envp[])
```

Parameters

- **host**: host name or IP address of the host machine where the process is to be created
- **path**: complete path to the executable program, including file name and relative or absolute directory, when appropriate
- **args**: null terminated array of arguments to be provided to the executable
- **envp**: null terminated array of environment variables to be provided to the executable

Description

This function creates a process on the specified host. The process is created in a stopped state, and a connection is established that allows the client to insert instrumentation into the created process. The process must be started to begin execution.

Note that bcreate does not return control to the caller until the new process has been created or failed to be created. The return value indicates whether the operation succeeded or failed.

Return value

The return value for bcreate indicates whether the process was successfully created.

- **ASC_success**: process was successfully created, as expected
- **ASC_operation_failed**: process failed to be created

See Also

bdestroy, bstart, create, destroy, start
13.10 bdeactivate_probe

Synopsis

#include <Process.h>

AisStatus bdeactivate_probe(short count, ProbeHandle *phandle)

Parameters

count number of probes to be deactivated
phandle array of probe handles, representing the probes, to be deactivated

Description

This function accepts an array of probe handles as an input parameter. Each probe handle in
the array represents a probe that has been installed in the application. The client sends a
request to each of the processes within the application to deactivate the list of probes repre-
sented by the array. Probes are deactivated atomically for each process in the sense that the
process is temporarily stopped, all probes on the list are deactivated, then the process is
resumed. None of the probes in the array are left active.

phandle is an input array generated by an install_probe or binstall_probe call.
It is supplied by the caller and must contain at least count elements. The i\textsuperscript{th} element of the
array is a handle, or identifier, that identifies the i\textsuperscript{th} probe expression.

Note that bdeactivate_probe does not return control to the caller until all probes in the
array have been deactivated on the process. The return value indicates whether all probes in
the list were deactivated or one or more probes were left intact.

Return value

The return value for bdeactivate_probe indicates whether the deactivations were suc-
cessfully completed.

ASC_success all probe deactivations completed as expected
ASC_operation_failed all probe deactivations failed

See Also
13.11 bdestroy

Synopsis

#include <Process.h>
AisStatus bdestroy(void)

Description

This function destroys or terminates the processes.
Note that bdestroy does not return control to the caller until the process has been destroyed
or has failed to be destroyed. The return value indicates whether the termination succeeded or
failed.

Return value

The return value for bdestroy indicates whether the termination successfully completed.
ASC_success process was successfully terminated, as expected
ASC_operation_failed ???

See Also
13.12 bdetach

Synopsis

```c
#include <Process.h>

AisStatus bdetach(void)
```

Description

This function detaches the process. Process control flow, such as stepping and setting break points, can only be done while a process is in an attached state. Detaching a process removes the level of process control available to the client or tool when the process is attached, but retains the process connection so probe installation, activation, removal, etc. can still take place.

Note that `bdetach` does not return control to the caller until the process has been detached or failed to do so. The return value indicates whether the process successfully detached or failed to detach.

Return value

The return value for `bdetach` indicates whether the process was successfully detached.

- `ASC_success` : process was successfully detached, as expected
- `ASC_operation_failed` : process failed to detach

See Also

- `attach`, `battach`, `detach`
13.13 bdisconnect

Synopsis

#include <Process.h>
AisStatus bdisconnect (void)

Description

Disconnect from the process. Disconnecting from an application process removes the application environment created by a connection. All instrumentation and data are removed from the application process.

Note that bdisconnect does not return control to the caller until the process has either succeeded or failed in disconnecting.

Return value

The return value for bdisconnect indicates whether the connection was successfully terminated.

ASC_success connection was successfully terminated as expected
ASC_operation_failed connection failed to terminate

See Also
13.14 bexecute

Synopsis

```c
#include <Process.h>
AisStatus bexecute(ProbeExp pexp)
```

Parameters

- `pexp`: probe expression to be executed in the application process

Description

This function executes a probe expression within the application process. The expression is executed once, then removed. The application process is interrupted, the expression is executed, then the process resumes execution as before the interruption.

Note that `bexecute` does not return control to the caller until the probe expression has either succeeded or failed to execute.

Return value

The return value for `execute` indicates whether the request for deallocation succeeded or failed.

- `ASC_success`: probe expression was successfully executed
- `ASC_operation_failed`: attempt to execute the probe expression failed

See Also

- `execute`
13.15 bfree

Synopsis

#include <Process.h>

AisStatus bfree(ProbeExp pexp)

Parameters

pexp dynamically allocated block of probe memory

Description

This function deallocates a block of dynamically allocated probe memory in an application process. The probe expression must contain only a single reference to a block of data allocated by the malloc or bmalloc functions.

Note that bfree does not return control to the caller until deallocating the block of memory has either succeeded or failed.

Return value

The return value for bfree indicates whether the requests for deallocation were successfully executed.

See Also
13.16 binstall_probe

Synopsis

```c
#include <Process.h>
AisStatus binstall_probe(
    short count,
    ProbeExp *probe_exp,
    InstPoint *point,
    GCBFuncType *data_cb_fp,
    GCBTagType *data_cb_tag,
    ProbeHandle *phandle)
```

Parameters

- **count**: number of probe expressions to be installed
- **probe_exp**: probe expressions to be installed
- **point**: instrumentation points where the probe expressions are to be installed
- **data_cb_fp**: callback functions to process data received from the probe expression
- **data_cb_tag**: tags to be used as an argument to the data callback when it is invoked
- **phandle**: probe handles that represent the installed probe expressions

Description

This function installs probe expressions as instrumentation at specific locations within the process. Probe expressions are installed atomically, in the sense that within a process either all probe expressions in the request are installed into the process, or none of the expressions are installed. The return value indicates whether all probes were installed, or whether the process was unable to install the expressions as requested.

**Data_cb_fp** is an input array supplied by the caller that must contain at least **count** elements. The \( i^{th} \) element of the array is a pointer to a callback function that is invoked each time the \( i^{th} \) probe in **phandle** sends data via the **AisSendMsg** function. **Data_cb_tag** is a similar array that contains the callback tag used when callbacks in **data_cb_fp** are invoked. The \( i^{th} \) callback tag is used with the \( i^{th} \) callback.

**Phandle** is an output array supplied by the caller that must contain at least **count** elements. The \( i^{th} \) element of the array is a handle, or identifier, to be used in subsequent references to the \( i^{th} \) probe expression. For example, it is needed when the client activates, deactivates or removes a probe expression from an application or process. **Phandle** does not contain valid information if the installation fails.
Note that `binstall_probe` does not return control to the caller until all probe expressions have been installed or failed to install within the process.

**Return value**

The return value for `binstall_probe` indicates whether the probe installations were successful.

- `ASC_success` all probes were successfully installed, as expected
- `ASC_operation_failed` one or more of the probes could not be installed as requested, so none of the probes were installed

**Callback Data**

The callback function is invoked once for each message sent from the probe. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback tag is given in the `data_cb_tag` array. The callback message is the data send by the probe using the `Ais_send` function call.

**See Also**

- `Ais_send`, `install_probe`, ...

13.17 bload_module

Synopsis

#include <Process.h>
AisStatus bload_module(ProbeModule *module)

Parameters

Description

This function is currently being designed. The intent is to provide some means by which instrumentation functions and probe classes might be loaded into a process for use by one or more probe expressions.

Note that bload_module does not return control to the caller until the probe module has been installed or failed to install in the process.

Return value

The return value for bload_module indicates whether the probe module installation was successful.
ASC_success module was successfully installed on all processes
ASC_operation_failed module could not be installed as requested on one or more processes

See Also

bunload_module, load_module, unload_module
13.18 bmalloc

Synopsis

#include <Process.h>

ProbeExp bmalloc(ProbeType pt, void *init_val, AisStatus &stat)

ProbeExp bmalloc(
    ProbeType pt,
    void *init_val,
    Phase ps,
    AisStatus &stat)

Parameters

pt  data type of the allocated data
init_val  pointer to the initial value of the allocated data, or 0 if no initial value is desired
ps  phase that will contain the allocated data
stat  output value indicating the completion status of the function

Description

This function allocates a block of probe data in a process. It returns a single probe expression that may be used to reference the allocated data. The data may be referenced in a probe expression that may be installed in the process.

Note that bmalloc does not return control to the caller until it has either succeeded or failed on the process. If the allocation succeeds it returns a valid probe expression data reference and stat is given the value ASC_success. If the allocation fails then stat is given the value ASC_operation_failed and any probe that references the returned value of bmalloc will fail to install.

Return value

A probe expression that may be used as a valid reference to the data on this process.

See Also

bfree, free, malloc
13.19 breadmem

Synopsis

#include <Process.h>
AisStatus breadmem(char *location, char *buffer, int size)

Parameters

location address in the application process where reading is to begin
buffer address in the client process where data is to be placed
size size, in bytes, of both the buffer and the memory block to be read

Description

This function sends a request to the daemon managing this process to read the indicated block of memory within the process. The block of memory is then returned to the client and stored in the indicated buffer.

Note that breadmem does not return control to the caller until the memory has been read or failed to be read from the process.

Return value

The return value for breadmem indicates whether the block of memory was successfully read from the application process.

ASC_success memory was successfully read, as expected
ASC_operation_failed memory could not be read

See Also

bwritemem, readmem, writemem
13.20 bremove_phase

Synopsis

#include <Process.h>
AisStatus bremove_phase(Phase ps)

Parameters

ps phase description to be removed from the application

Description

This function removes a phase from the application. Data and functions associated with the phase are unaffected by removing the phase. Existing probe data cannot become associated with a phase except at the time of data allocation, so deleting a phase has the effect of permanently disassociating data from any phase.

Note that bremove_phase does not return control to the caller until the phase has been removed or failed to be removed from the process.

Return value

The return value for bremove_phase indicates whether the phase was successfully removed from the process.

ASC_success phase was successfully removed, as expected
ASC_operation_failed phase could not be removed from the process

See Also

add_phase, badd_phase, class Phase, remove_phase
13.21 bremove_probe

Synopsis

```c
#include <Process.h>

AisStatus bremove_probe(short count, ProbeHandle *phandle)
```

Parameters

- `count` number of probe handles in the accompanying array
- `phandle` array of probe handles representing probe expressions to be removed

Description

This function deletes or removes probe expressions that have been installed in a process. If all probe expressions are installed and deactivated, the probe expressions are removed and a "normal" return status results. If one or more of the probe expressions are currently active, the expressions are deactivated and removed, and the return status indicates there were active probes at the time of their removal. If one or more of the probes do not exist, all existing probes are removed and the return status indicates an appropriate warning. If one or more of the probe expressions exists but cannot be removed, an error results and none of the probe expressions is removed. If the process is not connected a warning is returned.

`Phandle` is an input array generated by an `install_probe` or `binstall_probe` call. It is supplied by the caller and must contain at least `count` elements. The `i^{th}` element of the array is a handle, or identifier, that identifies the `i^{th}` probe expression.

Probe expression removal is atomic in the sense that all probe expressions are removed from a given process or none are. When probes are removed from a process the process is temporarily stopped, all indicated probes are removed, and the process is resumed.

Note that `bremove_probe` does not return control to the caller until the probes have been removed or failed to be removed from the process. If one or more probes cannot be removed for any reason, as many as can are removed and status indicates the condition.

Return value

The return value for `bremove_probe` indicates whether all probes in the list were successfully removed from the process.

- `ASC_success` all probes were successfully removed, as expected
- `ASC_operation_failed` one or more of the probes were not removed

See Also

`bactivate_probe`, `bdeactivate_probe`, `binstall_probe`, `activate_probe`, `deactivate_probe`, `install_probe`, `remove_probe`
13.22 bresume

Synopsis

```c
#include <Process.h>

AisStatus bresume(void)
```

Description

This function resumes execution of a process that has been temporarily suspended by a `stop` or `bstop` function call. A process must be connected, attached and stopped for it to be resumed. A process that is not connected or not attached will result in a warning return code. A process that is not stopped will result in an informational return code.

Note that `bresume` does not return control to the caller until the process has resumed or failed to resume.

Return value

The return value for `bresume` indicates whether the process was successfully resumed.

- `ASC_success` process was resumed, as expected
- `ASC_operation_failed` process failed to be resumed

See Also

- `attach`, `battach`, `bconnect`, `bdetach`, `bdisconnect`, `bsuspend`, `connect`, `detach`, `disconnect`, `resume`, `suspend`
13.23 bset_phase_period

Synopsis

#include <Process.h>

AisStatus bset_phase_period(Phase ps, float period)

Parameters

ps phase to be modified
period new time interval between successive phase activations, in seconds

Description

This function changes the time interval between successive activations of a phase within the process. Processes which do not have the phase installed result in an informational return code. Processes that are not connected result in a warning return code.

The new period is represented by a floating-point value. If the value is positive it represents the time interval in seconds. If the value is zero or positive and smaller than the minimum activation time interval, it represents the minimum activation delay time. In both cases the phase is activated immediately before setting the new interval. If the value is less than zero the phase is disabled immediately, but left in place for possible future reactivation.

Note that bset_phase_period does not return control to the caller until the phase period has been set or failed to be set in the process.

Return value

The return value for bset_phase_period indicates whether the phase period was successfully set on this process.

ASC_success phase period was successfully set
ASC_operation_failed phase period failed to be set

See Also

add_phase, badd_phase, bremove_phase, get_phase_period, remove_phase, set_phase_period
13.24 bsignal

Synopsis

```c
#include <Process.h>
AisStatus bsignal(int unix_signal)
```

Parameters

- `unix_signal`  Unix™ signal to be sent to every process in the application

Description

This function sends the specified signal to the process. The process must be both connected and attached to receive the signal. The function does not return until the process receives and acknowledges receiving the signal.

A signal is sent only to those processes that are connected and attached.

Note that `bsignal` does not return control to the caller until the process has been signalled or failed to be signalled.

Return value

The return value for `bsignal` indicates whether the AIX signal was successfully sent to the process.

- `ASC_success`  signal was successfully sent to the process
- `ASC_operation_failed`  signal failed to be sent to the process

See Also
13.25 bstart

Synopsis

```c
#include <Process.h>
AisStatus bstart(void)
```

Description

This function starts the execution of a process that has been created but not yet begun execution. When applied to a process that has begun execution it causes the process to terminate and restart.

Note that `bstart` does not return control to the caller until the process has started or failed to start.

Return value

The return value for `bstart` indicates whether the process was successfully started.

- `ASC_success` process was started
- `ASC_operation_failed` process failed to be started

See Also

- `bcreate`, `bdestroy`, `create`, `destroy`, `start`
13.26 bsuspend

Synopsis

#include <Process.h>
AisStatus bsuspend(void)

Description

This function suspends a process that is executing. A tool must be both connected and
attached to a process in order to suspend process execution.

Note that bsuspend does not return control to the caller until the process has been sus-
pended or failed to be suspended.

Return value

The return value for bsuspend indicates whether all processes within the application were
successfully suspended.

ASC_success process was successfully suspended
ASC_operation_failed process failed to be suspended

See Also

bresume, resume, suspend
**13.27 bunload_module**

*Synopsis*

```
#include <Process.h>
AisStatus bunload_module(ProbeModule* module)
```

*Parameters*

- **module**: probe module to be removed from the application process

*Description*

This function is currently being designed. The intent is to provide some means by which previously loaded instrumentation functions and probe classes might be removed from a process. Note that **bunload_module** does not return control to the caller until the probe module has been removed or failed to be removed from the application process.

*Return value*

The return value for **bunload_module** indicates whether the probe module was successfully removed from the process.

- **ASC_success**: module was successfully removed from the process
- **ASC_operation_failed**: module could not be removed from the process

*See Also*

- **bload_module**, **load_module**, **unload_module**
13.28 b writemem

Synopsis

AisStatus b writemem(char *location, char *buffer, int size)

Parameters

  location       address in the application process where writing is to begin
  buffer         address in the client process from which data is to be taken
  size           size, in bytes, of both the buffer and the memory block to be written

Description

This function sends a request to the daemon managing this process to write the indicated block of memory within the process. Data to write the block of memory is taken from the indicated client buffer.

Note that b writemem does not return control to the caller until the memory has been written or failed to be written on the process.

Return value

The return value for b writemem indicates whether the block of memory was successfully written to the application process.

ASC_success       memory was successfully written, as expected
ASC_operation_failed  memory could not be written

See Also

  breadmem, readmem, writemem
13.29 connect

Synopsis

```c
#include <Process.h>
AisStatus connect(GCBFuncType fp, GCBTagType tag)
```

Parameters

- **fp**: callback function to be invoked with each successful or failed connection to a process listed within the application
- **tag**: callback tag to be used each time the callback function is invoked

Description

Connection to a process establishes a communication channel to the CPU where the process resides (the host CPU) and creates the environment within that process that allows the client to insert and remove instrumentation, alter its control flow, etc.

Note that the function submits the requests to connect the process and returns immediately. The callback function receives notification of a connection’s success or failure.

Return value

The return value for `connect` indicates whether the request for connection was successfully submitted, but indicates nothing about whether the request was successfully executed.

- **ASC_success**: connection request was successfully submitted
- **ASC_operation_failed**: request could not be submitted

Callback Data

The callback function is invoked once for each process for which a connection is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- **ASC_success**: connection was successfully established on this process
- **ASC_operation_failed**: attempt to connect to this process failed

See Also
### 13.30 create

**Synopsis**

```c
#include <Process.h>

AisStatus create(
    const char *host,
    const char *path,
    char *const args[],
    char *const envp[],
    GCBFuncType fp,
    GCBTagType tag)
```

**Parameters**

- **host**: host name or IP address of the host machine where the process is to be created
- **path**: complete path to the executable program, including file name and relative or absolute directory, when appropriate
- **args**: null terminated array of arguments to be provided to the executable
- **envp**: null terminated array of environment variables to be provided to the executable
- **fp**: callback function to be invoked with a successful or failed creation
- **tag**: callback tag to be used when the callback function is invoked

**Description**

This function is currently being defined. It creates an application in a “stopped” state.

Note that `create` returns control immediately to the caller. It does not wait until the process has been created. The return value indicates whether the request was successfully submitted and gives no indication whatever about the success or failure of the execution of the request.

**Return value**

The return value for `create` indicates whether the request for process creation was successfully submitted, but indicates nothing about whether the request was successfully executed.

- `ASC_success`: process creation request was successfully submitted
- `ASC_operation_failed`: request could not be submitted
Callback Data

The callback function is invoked once when the new process is created. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

- **ASC_success** connection was successfully established on this process
- **ASC_operation_failed** attempt to connect to this process failed

See Also

bcreate, bdestroy, bstart, destroy, start
13.31 deactivate_probe

Synopsis

```c
#include <Process.h>
AisStatus deactivate_probe(
    short count,
    ProbeHandle *phandle,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- **count**: number of probes to be deactivated
- **phandle**: array of probe handles, representing the probes, to be deactivated
- **ack_cb_fp**: acknowledgement callback function to be invoked when all probe expressions in the array have been deactivated (or deactivation fails)
- **ack_cb_tag**: tag to be used with the acknowledgement callback function

Description

This function accepts an array of probe handles as an input parameter. Each probe handle in the array represents a probe that has been installed in the application. The client sends a request to each of the processes within the application to deactivate the list of probes represented by the array. Probes are deactivated atomically for each process in the sense that the process is temporarily stopped, all probes on the list are deactivated, then the process is restarted. None of the probes in the array are left active. If one or more probes cannot be deactivated, for whatever reason, all that can be deactivated are deactivated.

`phandle` is an input array generated by an `install_probe` or `binstall_probe` call. It is supplied by the caller and must contain at least `count` elements. The `i`th element of the array is a handle, or identifier, that identifies the `i`th probe expression.

Note that `deactivate_probe` returns control immediately to the caller. It does not wait until all probes in the array have been deactivated on all processes in the application. The return value indicates whether the request was successfully submitted and gives no indication whatever about the success or failure of the execution of the request.

Return value

The return value for `deactivate_probe` indicates whether the deactivations were successfully submitted.

- **ASC_success**: all probe deactivations were submitted, as expected
- **ASC_operation_failed**: one or more of the probe deactivations were not submitted
Callback Data

The callback function is invoked once for each process for which a probe deactivation is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` probes were successfully deactivated on this process
- `ASC_operation_failed` attempt to deactivate probes on this process failed

See Also
13.32 destroy

Synopsis

```c
#include <Process.h>

AisStatus destroy(GCBFuncType fp, GCBTagType tag)
```

Parameters

- `fp`: acknowledgement callback function to be invoked for each process that is destroyed (or not destroyed)
- `tag`: tag to be used with the acknowledgement callback function

Description

This function destroys or terminates all processes within the application.

Note that `destroy` returns control to the caller immediately. It does not wait until all processes within the application have been destroyed. The return value indicates whether the requests were successfully submitted, but give not indication of whether the requests themselves were successfully executed.

Return value

The return value for `destroy` indicates whether the terminations were successfully requested.

- `ASC_success`: all terminations were successfully requested, as expected
- `ASC_operation_failed`: one or more of the terminations were not requested

Callback Data

The callback function is invoked once when the process destruction is attempted. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success`: process was successfully destroyed
- `ASC_operation_failed`: attempt to destroy this process failed

See Also
13.33 detach

Synopsis

```c
#include <Process.h>
AisStatus detach(GCBFuncType fp, GCBTagType tag)
```

Parameters

- `fp`: callback function to be invoked when detaching from a process succeeds or fails.
- `tag`: callback tag to be used when the callback function is invoked.

Description

This function detaches the client from this process. Process control flow, such as stepping and setting break points, can only be done while a process is in an attached state. Detaching a process removes the level of process control available to the client or tool when the process is attached, but retains the process connection so probe installation, activation, removal, etc. can still take place.

Note that `detach` returns control to the caller immediately upon issuing a request to detach from a process. The return value indicates whether the request was successfully submitted.

Return value

The return value for `detach` indicates whether the request was successfully submitted.
- `ASC_success`: detach request was successfully submitted, as expected
- `ASC_operation_failed`: request was not submitted

Callback Data

The callback function is invoked once for each process for which detachment is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:
- `ASC_success`: process was successfully detached
- `ASC_operation_failed`: attempt to detach this process failed

See Also

- `attach`, `battach`, `bdetach`
13.34 disconnect

Synopsis

```c
#include <Process.h>

AisStatus disconnect(GCBFuncType fp, GCBTagType tag)
```

Parameters

- `fp` callback function to be invoked when disconnection from a process succeeds or fails.
- `tag` callback tag to be used when the callback function is invoked.

Description

Disconnecting from an application process removes the application environment created by a connection. All instrumentation and data are removed from the application process.

Note that the function submits the request to disconnect the process and returns immediately. The callback function receives notification of a disconnection’s success or failure.

Return value

The return value for `disconnect` indicates whether the request for disconnection was successfully submitted, but indicates nothing about whether the request was successfully executed.

Callback Data

The callback function is invoked once when the process is (or fails to be) disconnected. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` process was successfully disconnected
- `ASC_operation_failed` attempt to disconnect this process failed

See Also
13.35 execute

Synopsis

```c
#include <Process.h>
AisStatus execute(
    ProbeExp probe_exp,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `probe_exp`: probe expression to be executed in the application process
- `ack_cb_fp`: callback function to be invoked when execution succeeds or fails
- `ack_cb_tag`: callback tag to be used when the callback function is invoked

Description

This function executes a probe expression within the application process. The expression is executed once, then removed. The application process is interrupted, the expression is executed, then the process resumes execution as before the interruption.

Note that `execute` returns control to the caller immediately upon submitting its request to the daemon. It does not wait until the probe expression has been executed or failed to execute. The acknowledgement callback function receives notification of the success or failure of the execution.

Return value

The return value for `execute` indicates whether the request for deallocation was successfully submitted, but indicates nothing about whether the request was successfully executed.

- `ASC_success`: probe expression execution was successfully submitted
- `ASC_??`: probe expression execution was successfully submitted

Callback Data

The callback function is invoked once when execution succeeds or fails. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success`: probe expression was successfully executed
- `ASC_operation_failed`: attempt to execute the probe expression failed

See Also

`bexecute`
13.36 free

Synopsis

```c
#include <Process.h>
AisStatus free(
    ProbeExp pexp,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `pexp` dynamically allocated block of probe memory
- `ack_cb_fp` callback function to be invoked when deallocating the block of memory succeeds or fails
- `ack_cb_tag` callback tag to be used when the callback function is invoked

Description

This function deallocates a block of dynamically allocated probe memory for this process. The probe expression must contain only a single reference to a block of data allocated by the `malloc` or `bmalloc` functions.

Note that `free` returns control to the caller immediately upon submitting its request to free the data. It does not wait until the data has been deallocated or failed to deallocate. The acknowledgement callback function receives notification of the success or failure of the deallocation.

Return value

The return value for `free` indicates whether the request for deallocation was successfully submitted, but indicates nothing about whether the request was successfully executed.

Callback Data

The callback function is invoked once when deallocation succeeds or fails. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` block of probe memory was successfully deallocated
- `ASC_operation_failed` attempt to deallocate memory on this process failed

See Also
13.37 get_pid

Synopsis

```c
#include <Process.h>

int get_pid(void) const
```

Description

This function returns the AIX process identification number for the indicated process.

Return value

AIX process ID.

See Also
13.38 getPhasePeriod

Synopsis

```c
#include <Process.h>

float getPhasePeriod(Phase ps, AisStatus &stat) const
```

Parameters

- `ps`: phase being queried on this process
- `stat`: output variable that indicates the success or failure of the call

Description

This function returns the time duration, in seconds, between successive activations of this phase. If the return value is greater than zero, the value represents the minimum time between successive activations of the phase. Due to scheduling conflicts with other processes and resources on the system the actual time between phase activations may be greater than the stated value. If the return value is zero it represents the fastest rate of phase activation possible. If the return value is less than zero, it indicates an error.

`stat` indicates whether the query was successful. To be successful the process must be connected and the phase must exist on the process.

Return value

Minimum time duration, in seconds, between successive activations of this phase.

See Also
13.39 get_program_object

Synopsis

```c++
#include <Process.h>

SourceObj get_program_object(void) const
```

Description

This function retrieves the top-level source object from the process. Source objects are a coarse source-level view of the program structure. Program objects represent the top level of a tree structure. Below a program object are modules, then data and functions, etc. If the process is not connected or some other error occurs, the source object returned will be invalid. The source object may be queried to determine its validity.

Return value

Program object for this process.

See Also

class SourceObj
13.40 get_task

Synopsis

```c
#include <Process.h>

int get_task(void) const
```

Description

This function returns the task identifier associated with this process.

Return value

Task ID for this process.
13.41 install_probe

Synopsis

```c
#include <Process.h>
AisStatus install_probe(
    short count,
    ProbeExp *probe_exp,
    InstPoint *point,
    GCBFuncType *data_cb_fp,
    GCBTagType *data_cb_tag,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag,
    ProbeHandle *phandle)
```

Parameters

- **count**: number of probe expressions to be installed, instrumentation points, data callback functions, data callback tags, and probe handles
- **probe_exp**: probe expressions to be installed
- **point**: instrumentation points where the probe expressions are to be installed
- **data_cb_fp**: callback function to process data received from the probe expression
- **data_cb_tag**: tag to be used as an argument to the data callback when it is invoked
- **ack_cb_fp**: callback function to process data received from the probe expression
- **ack_cb_tag**: tag to be used as an argument to the data callback when it is invoked
- **phandle**: probe handles that represent the installed probe expressions

Description

This function installs probe expressions as instrumentation at specific locations within a process. Probe expressions are installed atomically, in the sense that within each process either all probe expressions in the request are installed into the process, or none of the expressions are installed. The return value indicates whether the request to have probes installed was successfully submitted.

**Phandle** is an output array supplied by the caller that must contain at least **count** elements. The *i*\(^{th}\) element of the array is a handle, or identifier, to be used in subsequent references to the *i*\(^{th}\) probe expression. For example, it is needed when the client activates, deactivates or removes a probe expression from an application or process. **Phandle** does not contain valid information if the installation fails.
Note that `install_probe` returns control to the caller immediately upon submitting all requests to the daemons. It does not wait until all probe expressions have been installed or failed to install within all processes within the application.

**Return value**

The return value for `install_probe` indicates whether the request for probes to be installed was successfully submitted. It gives no indication of whether the requests was successfully executed.

- **ASC_success**: probe expression installation request was successfully submitted
- **ASC_operation_failed**: probe expression installations failed to be requested

**Callback Data**

- **ack_cb_fp**: The callback function is invoked once and removed. It is called when the status message for this request is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:
  - **ASC_success**: all probes were successfully installed in this process
  - **ASC_operation_failed**: attempt to install probes in this process failed

- **data_cb_fp**: The callback function is invoked once for each message sent from the probe. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback tag is given in the `data_cb_tag` array. The callback message is the data send by the probe using the `Ais_send()` function call.

**See Also**

- `activate_probe`, `bactivate_probe`, `bdeactivate_probe`, `bremove_probe`, `deactivate_probe`, `remove_probe`
13.42 load_module

Synopsis

#include <Process.h>

AisStatus load_module(
    ProbeModule *module,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)

Parameters

Description

This function is currently being designed. The intent is to provide some means by which instrumentation functions and probe classes might be loaded into an application for use by one or more probe expressions.

Note that load_module returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the module has been loaded or failed to load within the process.

Return value

The return value for load_module indicates whether the request to load the indicated module was successfully submitted. It gives no indication of whether the request was successfully executed.

ASC_success load requests was successfully submitted
ASC_operation_failed load operation failed to be requested

Callback Data

The callback function is invoked once for the process for which disconnection is requested. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

ASC_success objects were successfully loaded into this process
ASC_operation_failed attempt to load objects on this process failed

See Also
### 13.4.3 `malloc`

**Synopsis**

```c
#include <Process.h>

ProbeExp malloc(
    ProbeType pt,
    void *init_val,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag,
    AisStatus &stat)
```

```c
ProbeExp malloc(
    ProbeType pt,
    void *init_val,
    Phase ps,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag,
    AisStatus &stat)
```

**Parameters**

- **pt**
  - data type of the allocated data
- **init_val**
  - pointer to the initial value of the allocated data, or 0 if no initial value is desired
- **ps**
  - phase that will contain the allocated data
- **ack_cb_fp**
  - callback function to process the acknowledgement message
- **ack_cb_tag**
  - tag to be used as an argument to the acknowledgement callback when it is invoked
- **stat**
  - output value indicating the completion status of the function

**Description**

This function allocates a block of probe data in a process. It returns a single probe expression that may be used to reference the allocated data. The data may be referenced in a probe expression that may be installed in the process.

Note that `malloc` returns control to the caller immediately and does not wait until it has either succeeded or failed on the process. The probe expression representing the allocation is
returned immediately whether or not allocation succeeds. The returned probe expression may be used as a data reference on the process if the allocation succeeds. If the data reference is used in another probe expression and the client attempts to install that probe expression in a process where the allocation failed, that probe expression will fail to install. Similarly, installation will fail if one attempts to install the probe in a process where the data was not allocated.

Stat indicates whether all requests for allocation were successfully submitted. If all requests are successfully submitted stat is given the value ASC_success. If some request cannot be submitted then stat is given the value ASC_operation_failed. It reflects the highest severity encountered.

**Return value**

A probe expression that may be used as a valid reference to the data on this process if the data is allocated

**Callback Data**

The callback function is invoked once, when the acknowledgement message is received, and then removed. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

- ASC_success data was successfully allocated in this process
- ASC_operation_failed attempt to allocate data in this process failed

**See Also**

bfree, bmalloc, free
**13.44 operator =**

*Synopsis*

```c
#include <Process.h>
Process &operator = (const Process &rhs)
```

*Parameters*

rhs right operand

*Description*

This function assigns the value of the right operand to the invoking object. The left operand is the invoking object. For example, “Process rhs, lhs; ... lhs = rhs;” assigns the value of rhs to lhs. Both values would then refer to the same process, if any.

*Return value*

A reference to the invoking object (i.e., the left operand).

*See Also*
13.45 readmem

Synopsis

```c
#include <Process.h>
AisStatus readmem(
    char *location,
    char *buffer,
    int size,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `location`: address in the application process where reading is to begin
- `buffer`: address in the client process where data is to be placed
- `size`: size, in bytes, of both the buffer and the memory block to be read
- `ack_cb_fp`: callback function to process data read from the process
- `ack_cb_tag`: tag to be used as an argument to the callback when it is invoked

Description

This function sends a request to the daemon managing this process to read the indicated block of memory within the process. The block of memory is then returned to the client in the indicated buffer.

Note that `readmem` returns control to the caller immediately. It does not wait until the memory has been read or failed to be read from the process.

Return value

The return value for `readmem` indicates whether the request to read the block of memory was successfully submitted. It gives no indication whether the request was successfully executed.

- `ASC_success`: request was successfully submitted, as expected
- `ASC_operation_failed`: request could not be submitted

Callback Data

The callback function is invoked once, when the data is received. The data is written to the buffer indicated in the `readmem` function call. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success`: memory was successfully read in this process
ASC_operation_failed  attempt to read memory in this process failed

See Also

b writemem, readmem, writemem
13.46 remove_phase

Synopsis

```cpp
#include <Process.h>

AisStatus remove_phase(
    Phase ps,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `ps`: phase description to be removed from the application
- `ack_cb_fp`: callback function to process phase removal acknowledgments
- `ack_cb_tag`: tag to be used as an argument to the callback when it is invoked

Description

This function removes a phase from the application. Data and functions associated with the phase are unaffected by removing the phase. Existing probe data cannot become associated with a phase except at the time of data allocation, so deleting a phase has the effect of permanently disassociating data from any phase.

Note that `remove_phase` returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the phase has been removed or failed to be removed from the process.

Return value

The return value for `remove_phase` indicates whether the request to remove the indicated phase on the process was successfully submitted. It gives no indication of whether the request was successfully executed.

- `ASC_success`: remove request was successfully submitted
- `ASC_operation_failed`: remove operation failed to be requested

Callback Data

The callback function is invoked once, when the acknowledgement of the completion of this operation is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success`: phase was successfully removed from this process
- `ASC_operation_failed`: attempt to remove phase from this process failed
See Also

add_phase, badd_phase, bremove_phase
13.47 remove_probe

Synopsis

```c
#include <Process.h>
AisStatus remove_probe(
    short count,
    ProbeHandle *phandle,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- **count**: number of probe handles in the accompanying array
- **phandle**: array of probe handles representing probe expressions to be removed
- **ack_cb_fp**: callback function to process probe removal acknowledgments
- **ack_cb_tag**: tag to be used as an argument to the callback when it is invoked

Description

This function deletes or removes probe expressions that have been installed in an application. If all probe expressions are installed and deactivated, the probe expressions are removed and a “normal” return status results. If one or more of the probe expressions are currently active, the expressions are deactivated and removed and the return status indicates there were active probes at the time of their removal. If one or more of the probes do not exist, all existing probes are removed and the return status indicates an appropriate warning. If one or more of the probe expressions exists but cannot be removed, an error results and none of the probe expressions is removed. If one or more processes are not connected, probe removal takes place within those that are connected, and a warning is issued.

`phandle` is an input array generated by an `install_probe` or `binstall_probe` call. It is supplied by the caller and must contain at least `count` elements. The `ith` element of the array is a handle, or identifier, that identifies the `ith` probe expression.

Probe expression removal is atomic in the sense that all probe expressions are removed from a given process or none are. When probes are removed from a process the process is temporarily stopped, all indicated probes are removed, and the process is resumed.

Note that `remove_probe` returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the probes have been removed or failed to be removed from the process.
Return value

The return value for remove_probe indicates whether the request to remove the indicated probes on the process was successfully submitted. It gives no indication of whether the request was successfully executed.

ASC_success all remove requests were successfully submitted
ASC_operation_failed remove operation failed to be requested to some process

Callback Data

The callback function is invoked once, when the acknowledgement of the completion of this operation is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type Ais-Status, which contains one of the following status values:

ASC_success probes were successfully removed from this process
ASC_operation_failed attempt to remove probes from this process failed

13.48 resume

Synopsis

```c
#include <Process.h>
AisStatus resume(GCBFuncType ack_cb_fp, GCBTagType ack_cb_tag)
```

Parameters

- `ack_cb_fp`: callback function to process process resumption acknowledgments
- `ack_cb_tag`: tag to be used as an argument to the callback when it is invoked

Description

This function resumes execution of an application that has been temporarily suspended by a `stop` or `bstop` function. Execution resumption occurs on a process by process basis. A process must be connected, attached and stopped for it to be resumed. A process that is not connected or not attached will result in a warning return code. A process that is not stopped will result in an informational return code.

Note that `resume` returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the process has resumed or failed to resume.

Return value

The return value for `resume` indicates whether the request to resume process execution was successfully submitted. It gives no indication of whether the request was successfully executed.

- `ASC_success`: request to resume execution was successfully submitted
- `ASC_operation_failed`: resume operation failed to be requested

Callback Data

The callback function is invoked once, when the acknowledgement of the completion of this operation is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success`: process was successfully resumed
- `ASC_operation_failed`: attempt to resume this process failed

See Also

- `attach`, `battach`, `bconnect`, `bdetach`, `bdisconnect`, `bresume`, `bsuspend`, `connect`, `detach`, `disconnect`, `suspend`
13.49 set_phase_period

Synopsis

```c
#include <Process.h>
AisStatus set_phase_period(
    Phase ps,
    float period,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

Parameters

- `ps` phase to be modified
- `period` new time interval between successive phase activations, in seconds
- `ack_cb_fp` callback function to process phase acknowledgments
- `ack_cb_tag` tag to be used as an argument to the callback when it is invoked

Description

This function changes the time interval between successive activations of a phase. The interval change occurs on a process by process basis for all processes within the application. Processes which do not have the phase installed result in an informational return code. Processes that are not connected result in a warning return code.

The new period is represented by a floating-point value. If the value is positive it represents the time interval in seconds. If the value is zero or positive and smaller than the minimum activation time interval, it represents the minimum activation time interval. In both cases the phase is activated immediately upon setting the new interval. If the value is less than zero the phase is disabled immediately, but left in place for possible future reactivation.

Note that `set_phase_period` returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the phase period has been set or failed to be set within the process.

Return value

The return value for `set_phase_period` indicates whether the request to set the phase period was successfully submitted. It gives no indication of whether the request was successfully executed.

- `ASC_success` request to set the phase period was successfully submitted
- `ASC_operation_failed` set phase period failed to be requested
Callback Data

The callback function is invoked once, when the acknowledgement of the completion of this operation is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

- ASC_success phase period was successfully set
- ASC_operation_failed attempt to set the phase period on this process failed

See Also

add_phase, badd_phase, bremove_phase, bset_phase_period, get_phase_period, remove_phase
13.50 signal

Synopsis

```c
#include <Process.h>
AisStatus signal(
    int unix_signal,
    GCBFuncType fp,
    GCBTagType tag)
```

Parameters

- `unix_signal` Unix™ signal to be sent to this process
- `ack_cb_fp` callback function to process the signal acknowledgment
- `ack_cb_tag` tag to be used as an argument to the callback when it is invoked

Description

This function sends the specified signal to the process. The process must be both connected and attached to receive the signal.

A signal is sent to a process if it is connected and attached.

Note that `signal` returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the process has been signaled or failed to be signalled.

Return value

The return value for `signal` indicates whether the request to signal the process was successfully submitted. It gives no indication of whether the request was successfully executed.

- `ASC_success` request to signal the processes was submitted
- `ASC_operation_failed` signalling failed to be requested

Callback Data

The callback function is invoked once, when the acknowledgement of the completion of this operation is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` process was successfully signaled
- `ASC_operation_failed` attempt to signal this process failed

See Also
13.51 start

Synopsis

#include <Process.h>

AisStatus start(GCBFuncType ack_cb_fp, GCBTagType ack_cb_tag)

Parameters

ack_cb_fp callback function to process a start acknowledgement
ack_cb_tag tag to be used as an argument to the callback when it is invoked

Description

This function is currently being designed. This function starts the execution of a process that has been created but has not yet begun execution.

Note that start returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the application has been started or failed to be started.

Return value

The return value for start indicates whether the request to start the process was successfully submitted. It gives no indication of whether the request was successfully executed.

ASC_success request to start the application was submitted
ASC_operation_failed start failed to be requested

Callback Data

The callback function is invoked once, when the acknowledgement of the completion of this operation is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

ASC_success process was successfully started
ASC_operation_failed attempt to start this process failed

See Also
13.52 suspend

Synopsis

#include <Process.h>

AisStatus suspend(GCBFuncType fp, GCBTagType tag)

Parameters

fp

callback function to process the suspend acknowledgement

tag

tag to be used as an argument to the callback when it is invoked

Description

This function suspends a process that is executing. A tool must be both connected and attached to a process in order to suspend process execution.

Note that suspend returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the application has been suspended or failed to be suspended.

Return value

The return value for suspend indicates whether the request to suspend execution of the process was successfully submitted. It gives no indication of whether the request was successfully executed.

ASC_success request to suspend the process was submitted
ASC_operation_failed suspend failed to be requested

Callback Data

The callback function is invoked once, when the acknowledgement of the completion of this operation is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

ASC_success process was successfully suspended
ASC_operation_failed attempt to suspend this process failed

See Also
### 13.53 unload_module

**Synopsis**

```c
#include <Process.h>

AisStatus unload_module(
    ProbeModule *module,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)
```

**Parameters**

**Description**

This function is currently being designed. The intent is to provide some means by which previously loaded instrumentation functions and probe classes might be removed from an application.

Note that `unload_module` returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the module has been removed or failed to be removed from the process.

**Return value**

The return value for `unload_module` indicates whether the request to remove the indicated module on the process was successfully submitted. It gives no indication of whether the request was successfully executed.

- `ASC_success` remove request was successfully submitted
- `ASC_operation_failed` remove operation failed to be requested

**Callback Data**

The callback function is invoked once, when the acknowledgement of the completion of this operation is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type `AisStatus`, which contains one of the following status values:

- `ASC_success` module was successfully removed from this process
- `ASC_operation_failed` attempt to remove module from this process failed

**See Also**

- `bload_module`, `bunload_module`, `load_module`
13.54 writemem

Synopsis

#include <Process.h>
AisStatus writemem(
    char *location,
    char *buffer,
    int size,
    GCBFuncType ack_cb_fp,
    GCBTagType ack_cb_tag)

Parameters

  location address in the application process where writing is to begin
  buffer address in the client process from which data is to be taken
  size size, in bytes, of both the buffer and the memory block to be written
  ack_cb_fp callback function to process a start acknowledgement
  ack_cb_tag tag to be used as an argument to the callback when it is invoked

Description

This function sends a request to the daemon managing this process to write the indicated block of memory within the process. Data to write the block of memory is taken from the indicated client buffer.

Note that writemem returns control to the caller immediately upon submitting the request to the daemon. It does not wait until the application has been suspended or failed to be suspended.

Return value

The return value for writemem indicates whether the request to write data into the memory of the process was successfully submitted. It gives no indication of whether the request was successfully executed.

  ASC_success request to write data was submitted
  ASC_operation_failed write failed to be requested

Callback Data

The callback function is invoked once, when the acknowledgement of the completion of this operation is received. When the callback is invoked the callback function is passed a pointer to the process as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:
ASC_success  
data was successfully written to process memory

ASC_operation_failed  
attempt to write data to this process failed

See Also

breadmem, readmem, writemem
14.0 class SourceObj

14.1 Supporting Data Types

14.1.1 Access

Synopsis

```
#include <SourceObj.h>
enum Access {
    SOA_unknown_access,
    SOA_shared,
    SOA_exclusive,
    SOA_LAST_ACCESS
}
```

Description

This enumeration type describes whether the source object to which it applies is part of a shared library or part of a non-shared library.

14.1.2 Binding

Synopsis

```
#include <SourceObj.h>
enum Binding {
    SOB_unknown_binding,
    SOB_static,
    SOB_dynamic,
    SOB_LAST_BINDING
}
```

Description

This enumeration type describes whether the source object to which it applies was bound statically or dynamically by the linker when references to external functions and data were resolved.
14.1.3 LpModel

Synopsis

#include <SourceObj.h>
enum LpModel {
    SOL_unknown_model,
    SOL_lp32,
    SOL_lp64,
    SOL_LAST_MODEL
}

Description

This enumeration type describes whether the source object to which it applies was compiled
and linked with the 32-bit address memory model or the 64-bit address memory model
enabled. All objects within a program are compiled and linked with the same model.

14.1.4SourceType

Synopsis

#include <SourceObj.h>
enum SourceType {
    SOT_unknown_type,
    SOT_program,
    SOT_module,
    SOT_function,
    SOT_data,
    SOT_loop,
    SOT_block,
    SOT_statement,
    SOT_LAST_TYPE
}

Description

This enumeration type describes whether the source object to which it applies represents a
whole program, module, function, data object, etc.
14.2 Constructors

Synopsis

```
#include <SourceObj.h>
SourceObj(void)
SourceObj(const SourceObj &copy)
```

Parameters

- `copy`: source object that will be duplicated in a copy constructor

Description

The default constructor creates an empty source object whose access, binding, LP model and source type are each set to “unknown”. The default constructor is invoked when uninitialized source objects are created, such as in arrays of source objects. Objects within the array can be overwritten using an assignment operator (`operator =`).

The copy constructor is used to transfer the contents of an initialized object (the `copy` parameter) to an uninitialized object.

Exceptions

- `ASC_insufficient_memory`: not enough memory to create a new node

See Also
14.3 address_end

Synopsis

#include <SourceObj.h>

void *address_end(void) const

Description

This function returns the virtual address of the last element associated with this source object. If the source object represents a scalar data object, then start_address and end_address return the same value. If the source object represents an array, then it returns the virtual address of the last element in the array. If the source object represents a function, then it returns the approximate address of the last instruction in the function.

Return value

Virtual address of the last element associated with this source object

See Also
14.4 address_start

Synopsis

    #include <SourceObj.h>
    
    void *address_start(void) const

Description

This function returns the virtual address of the first element associated with this source object. If the source object represents a scalar data object, then start_address and end_address return the same value. If the source object represents an array, then it returns the virtual address of the first element in the array. If the source object represents a function, then it returns the approximate address of the first instruction in the function.

Return value

    Virtual address of the first element associated with this source object

See Also
14.5 all_point

Synopsis

```
#include <SourceObj.h>
InstPoint all_point(int index) const
```

Parameters

- **index**: index into the instrumentation point table, which must be greater than or equal to zero, and less than `all_point_count()`.

Description

This function returns the instrumentation point indicated by the parameter `index`. All instrumentation points contained within this source object and its children are arranged in a table whose smallest index is 0 and whose largest index is `all_point_count()-1`.

Return value

Instrumentation point indicated by the parameter `index`.

See Also
14.6 all_point_count

Synopsis

    #include <SourceObj.h>
    int all_point_count(void) const

Description

This function returns the number of instrumentation points associated with this source object and all of its children.

Return value

Number of instrumentation points associated with this source object and all of its children.

See Also
14.7 bexpand

Synopsis

```c
#include <SourceObj.h>
AisStatus bexpand(const Process &proc)
```

Parameters

- `proc` process to which the “expand” request applies

Description

This function applies only to source objects with `SourceType` of `SOT_module`. The function requests that the details of an unexpanded module be supplied. Modules are not expanded when the client initially connects with a process. Modules that are not expanded cannot be examined for additional structure, such as data, functions, and instrumentation points. Recommended use is to establish a connection to a process, then expand those modules where one wishes to place instrumentation.

If the `SourceType` is not `SOT_module`, the function immediately returns with a status of `ASC_operation_failed`.

Note that the function submits the request to expand the source object and waits until the request has completed.

Return value

The return value indicates whether the request for expansion was successfully executed.

- `ASC_success` expansion was successfully completed
- `ASC_operation_failed` expansion failed

See Also
## 14.8 child

**Synopsis**

```c
#include <SourceObj.h>
SourceObj child(int index) const
```

**Parameters**

- `index` index into the source object child table, which must be greater than or equal to zero, and less than `child_count()`

**Description**

This function returns the child indicated by the parameter `index`. Index must be greater than or equal to zero, and less than `child_count()`. When `child()` is given an index value that is outside of this range, it returns an empty source object, as created by the default constructor. Children can be variables, functions, modules, etc.

**Return value**

Child source object indicated by the parameter `index`.

**See Also**
14.9 child_count

Synopsis

```
#include <SourceObj.h>

int child_count(void) const
```

Description

This function returns the number of child source objects associated with this source object. Empty source objects, created by the default constructor, return zero. Children can be variables, functions, modules, etc.

Return value

Number of child source objects associated with this source object.

See Also
14.10 expand

Synopsis

```
#include <SourceObj.h>
AisStatus expand(Process proc, GCBFuncType fp, GCBTagType tag)
```

Parameters

- proc: process to which the “expand” request applies

Description

This function applies only to source objects with SourceType of SOT_module. The function requests that the details of an unexpanded module be supplied. Modules are not expanded when the client initially connects with a process. Modules that are not expanded cannot be examined for additional structure, such as data, functions, and instrumentation points. Recommended use is to establish a connection to a process, then expand those modules where one wishes to place instrumentation.

If the SourceType is not SOT_module, the function immediately returns with a status of ASC_operation_failed.

Note that the function submits the request to expand the source object and returns immediately. It does not wait until the request has completed.

Return value

The return value for expand indicates whether the request was successfully submitted, but indicates nothing about whether the request itself was successfully executed.

Callback Data

The callback function is invoked once for each expansion request. When the callback is invoked the callback function is passed a pointer to the source object as the callback object. The callback message is the request status, of type AisStatus, which contains one of the following status values:

- ASC_success: process was successfully attached
- ASC_operation_failed: attempt to attach to this process failed

See Also

14.11 get_access

Synopsis

```
#include <SourceObj.h>

Access get_access(void) const
```

Description

This function returns the access type of the source object, that is, whether it is part of a shared library or not. Functions within a shared library are marked as SOA_shared. All others are designated SOA_exclusive. All variables are private to a program, even those in shared libraries, and are therefore marked SOA_exclusive.

Return value

- **SOA_shared**: object is a function from a shared library
- **SOA_exclusive**: object is not from a shared library, or it is data
- **SOA_unknown**: uninitialized object

See Also
14.12 get_binding

Synopsis

```c
#include <SourceObj.h>

Binding get_binding(void) const
```

Description

This function returns the binding type of the object. The binding type refers to whether the function or module is part of a dynamically loaded library. When it is part of a dynamic library `get_binding` returns `SOB_dynamic`. Otherwise it returns `SOB_static`.

Return value

- `SOB_dynamic` object is from a dynamically loaded library
- `SOB_static` object is not from a dynamically loaded library
- `SOB_unknown` uninitialized object

See Also
14.13 get_data_type

Synopsis

```c
#include <SourceObj.h>

ProbeType get_data_type(void) const
```

Description

This function returns the data type of the object when the object represents a function or a variable. When the object represents something that is neither a function nor a variable, it returns a data type tagged as “unknown”.

Return value

Data type of the object, or “unknown”.

See Also
14.14 get_demangled_name

Synopsis

#include <SourceObj.h>
const char *get_demangled_name(void) const

Description

This function returns the demangled name of a function. If the object is not contained within a
function it returns 0. A function demangled name is the name of a function as it appears in the
original source code of a program as seen by a compiler. Demangled names include parameter
data type information for some languages, notably C++ and Fortran 90, but not necessarily for
all languages.

Return value

Demangled function name when the object is a function, 0 otherwise.

See Also
14.15 get_mangled_name

Synopsis

#include <SourceObj.h>

char *const get_mangled_name(void) const

Description

This function returns the mangled name of an object when the object is a function. If the object is not contained within a function it returns 0. A function mangled name is the name of a function as it appears to the linker and loader. Name mangling is supported by compilers and linkers to resolve overloaded function names in object-oriented programming languages. In order to distinguish between two functions that have the same programmer-visible name, compilers encode parameter type information into the actual function name as it is seen by the linker and loader.

Return value

Mangled function name when the object is a function, 0 otherwise.

See Also
14.16 get_program_type

Synopsis

```c
#include <SourceObj.h>
LpModel get_program_type(void) const
```

Description

This function returns an indicator of whether the program is using the 32-bit address memory model, or the 64-bit address memory model. All functions within a program must use the same memory model. AIX does not support mixed address models.

Return value

- SOL_lp32: program uses the 32-bit address memory model
- SOL_lp64: program uses the 64-bit address memory model
- SOL_unknown: uninitialized object

See Also
14.17 get_variable_name

Synopsis

#include <SourceObj.h>
const char *get_variable_name(void) const

Description

This function returns the name of the object when the object is a data variable. It returns 0 when the object is not a variable.

Return value

Name of the object when the object is a data variable, 0 otherwise.

See Also
14.18 library_name

Synopsis

#include <SourceObj.h>

const char *library_name(void) const

Description

This function returns the name of the library that contains the object. When the object is not
contained within a library, or the library information has been removed from the executable,
this function returns 0.

Return value

Name of the library that contains the object, or 0.

See Also
14.19 line_end

Synopsis

#include <SourceObj.h>

int line_end(void) const

Description

This function returns the approximate line number of the last line in the object. When the line number is unknown or undefined, the function returns -1.

Return value

Approximate line number of the last line in the object, or -1.

See Also
14.20 line_start

Synopsis

```c
#include <SourceObj.h>

int line_start(void) const
```

Description

This function returns the approximate line number of the first line in the object. When the line number is unknown or undefined, the function returns -1.

Return value

Approximate line number of the first line in the object, or -1.

See Also
### 14.21 module_name

**Synopsis**

```c
#include <SourceObj.h>
const char *module_name(void) const
```

**Description**

This function returns the file name and path of the module that contains the object. If the object is the program object, which is not contained within any module, this function returns 0.

**Return value**

File name and path of the module that contains this object, or 0.

**See Also**
14.22 obj_parent

Synopsis

```c
#include <SourceObj.h>
SourceObj obj_parent(void) const
```

Description

This function returns the parent object of this object. For example, the parent object of a function object is a module object. The parent object of a program object is itself.

Return value

Parent object of the object.

See Also
14.23 operator =

Synopsis

```c
#include <SourceObj.h>
SourceObj &operator = (const SourceObj &copy)
```

Parameters

- `copy` source object to be duplicated

Description

This function transfers the contents of the `copy` parameter to the object.

Return value

Reference to the object.

See Also
14.24 operator ==

Synopsis

```c
#include <SourceObj.h>
int operator == (const SourceObj &compare)
```

Parameters

- `compare` : source object to be compared

Description

This function compares two source objects for equivalence. If the two objects represent the same portion of the program or application, this function returns 1. Otherwise it returns 0.

Return value

This function returns 1 if the two objects are equivalent, 0 otherwise.

See Also
14.25 operator !=

Synopsis

```cpp
#include <SourceObj.h>

int operator != (const SourceObj &compare)
```

Parameters

- `compare` source object to be compared

Description

This function compares two source objects for equivalence. If the two objects represent the same portion of the program or application, this function returns 0. Otherwise it returns 1.

Return value

This function returns 0 if the two objects are equivalent, 1 otherwise.

See Also
14.26 point

Synopsis

```
#include <SourceObj.h>
InstPoint point(int index) const
```

Parameters

- **index**: index into the instrumentation point table, which must be greater than or equal to zero, and less than `point_count()`.

Description

This function returns the instrumentation point indicated by the parameter `index`. Instrumentation points contained only within this source object are arranged in a table whose smallest index is 0 and whose largest index is `point_count()-1`.

Return value

Instrumentation point indicated by the parameter `index`.

See Also
**14.27 point_count**

*Synopsis*

```c
#include <SourceObj.h>
int point_count(void) const
```

*Description*

This function returns the number of instrumentation points associated with only this source object.

*Return value*

Number of instrumentation points associated with this source object.

*See Also*
14.28 program_name

Synopsis

    #include <SourceObj.h>

    const char *program_name(void) const

Description

This function returns the file name and path of the executable program (a.out), or 0 if the file name is not available.

Return value

File name and path of the executable, or 0 if it is not available.

See Also
14.29 reference

Synopsis

```c++
#include <SourceObj.h>

ProbeExp reference(void) const
```

Description

This function creates a reference to a program function or variable that may be used in a probe expression. References to program functions may be used in creating calls to those functions, while references to program variables may be used to read, modify, or write those variables. When the object does not represent a program function or variable, an “undefined” probe expression is returned.

Return value

Reference to the program function or data, or an “undefined” probe expression.

See Also
### 14.30 src_type

**Synopsis**

```c
#include <SourceObj.h>

SourceType src_type(void) const
```

**Description**

This function returns the type of source object represented by the object. The source object type corresponds to various objects within a program, such as modules, functions, variables, etc. If the source object does not correspond to a program or part of a program, the source object type is “unknown”.

**Return value**

Type of this source object.

**See Also**
15.0 Miscellaneous Functions

15.1 Ais_initialize

Synopsis

```c
#include <AisInit.h>

void Ais_initialize(void)
```

Description

This function is used to control the initialization and re-initialization of certain sub-systems, such as the registration of internal callbacks, within the instrumentation system. It must be called once before entering the main event loop.

See Also
15.2 AisMainLoop

Synopsis

```c
#include <AisMainLoop.h>
extern bool Ais_main_loop_done
void Ais_main_loop(void)
```

Description

This function is the main event loop for the instrumentation system. This loop processes events in the form of special messages from daemons and instrumented processes. It must be called after the initialization function. It must be called in order for the instrumentation system to process events and messages from the application processes. This function does not return control to the caller until Ais_main_loop_done is set to `done`, or the value 1.

See Also
16.0 Predefined Global Variables

16.1 Ais_main_loop_done

Synopsis

```
#include <AisMainLoop.h>
extern bool Ais_main_loop_done
```

Description

This variable is used to indicate to the main event loop that processing is to be terminated, and no more events are to be consumed. It does not cause any connections to be lost, nor to be closed. It only terminates the event processing loop that gathers event messages from all connected daemons.

16.2 Ais_msg_handle

Synopsis

```
#include <AisGlobal.h>
extern const ProbeExp Ais_msg_handle
```

Description

This constant represents a probe-specific value that is used to send messages from the probe to the client. Each probe is able to send messages to the client any time the probe is invoked. The client is able to distinguish between messages from one probe and messages from another. Furthermore, more than one client can be connected to an application process, and the probe must maintain some record of the client to whom it belongs. All the necessary information to accomplish these things is stored in the probe message handle. The probe message handle is used as the first argument to the Ais_send function, that sends a message to the client, to be processed by a client data callback function.
16.3 *Ais_send*

*Synopsis*

```c
#include <AisGlobal.h>
extern const ProbeExp Ais_send
```

*Description*

This constant represents a function that allows probes to send messages to the client. The function may be executed directly by the probe as any other function. The type signature for the send function is:

```c
void Ais_send( void *msg_handle, char *buffer, int size )
```

where *msg_handle* is the constant *Ais_msg_handle*, *buffer* is the message to be sent, and *size* is the number of bytes in the message.
