#### ON NEWTON-LIKE METHODS

by

#### James W. Daniel

#### l. Introduction.

Let X and Y be Banach spaces, P a twice continuously Frechet differentiable mapping of some open convex subset  $\Omega$  of X into Y, and  $\Gamma$  (x) a linear mapping of Y into X for each  $x \in \Omega$ , depending continuously on x. Many authors [1,3; see 2 for extensive bibliography] have considered Newton-like iterations of the form

(1) 
$$x_{n+1} = x_n - \Gamma(x_n) P(x_n), \quad x_0 \text{ given },$$

to compute a solution to the equation P(x) = 0. Generally speaking, one needs to have  $\Gamma(x)$  sufficiently near to  $\left[P^{\bullet}(x)\right]^{-1}$  to assure convergence;  $\Gamma(x) \equiv \left[P^{\bullet}(x)\right]^{-1}$  leads to the usual Newton method. To imitate the pure Newton method well, it would appear that  $\Gamma(x)$  should be near to a left inverse of  $P^{\bullet}(x)$ ; known theorems however show that in fact the crucial requirement is for  $\Gamma(x)$  to be nearly a right inverse of  $P^{\bullet}(x)$ , a fact clearly noted in [3]. In this short note we wish to point out that a type of convergence theorem can be stated even for  $\Gamma(x)$  nearly a left inverse, although the theorems do not contain the usual nearly computable error bounds and existence proofs one is accumstomed to seeing in this field.

### 2. Results.

Theorem 1. Let  $x* \in \Omega$  satisfy P(x\*) = 0. Suppose  $\|I - \Gamma(x*)P'(x*)\| \le \delta < 1$ . Then given any  $r \in (0, 1 - \delta)$ , there exists a neighborhood U of x\* in  $\Omega$  such that if x',  $n = 0, 1, \ldots$  and  $x_0$  are arbitrary points in U, the extended Newton-like iteration

(2)  $x_{n+1} = x_n - \Gamma(x_n')P(x_n) \text{, } n = 0, \dots \text{ converges to the solution}$   $x^* \text{ with rate of convergence given by } \|x_n - x^*\| \le (\delta + r)^n \|x_0 - x^*\| \text{.}$ 

Proof: Given  $r \in (0, 1 - \delta)$ , there exists a spherical neighborhood U of  $x^*$  in  $\Omega$  such that  $\|I - \Gamma(u)P'(v)\| \le \delta + r$  for  $u, v \in U$ , since  $\Gamma(x)$  and P'(x) are continuous. If  $x_0, x_1, \ldots x_R \in U$ , then  $x_{R+1}$  is defined and  $x_{R+1} - x^* = x_R - \Gamma(x_R')P(x_R) - (x^* - \Gamma(x_R')P(x^*))$ , so  $\|x_{R+1} - x^*\| \le \|x_R - x^*\| \|I - \Gamma(x_R')P'(x^* + \delta(x_R - x^*))\|$ ,  $0 < \delta < 1$ , and hence  $\|x_{R+1} - x^*\| \le (\delta + r)\|x_R - x^*\| < \|x_R - x^*\|$ , implying  $x_{R+1} \in U$  and also giving the error bound. Q.E.D.

The two special cases  $x_n' = x_n$ , or  $x_n' = x_0$ , yield the standard Newton-like and so called modified Newton-like methods. Newton's method itself is known to converge quadratically; following [3], it is possible to state sufficient conditions for the iteration (2) to converge more rapidly than given by the preceding theorem.

Theorem 2. Let  $\|P''(x)\| \le K_1$ ,  $\|\Gamma(x)\| \le K_2$  for  $x \in \Omega$ , and let  $x^* \in \Omega$  satisfy  $P(x^*) = 0$ . Suppose  $\|I - \Gamma(x^*)P'(x^*)\| \le \delta - 1$ ; let  $\delta_n \ge \|I - \Gamma(x_n^*)P'(x_n)\|$  and suppose that  $\delta_n$  satisfies  $\delta_{n+1} \le \delta_n^p$ ,  $1 . Then for a sufficiently small spherical neighborhood U of <math>x^*$ , the Newton-like sequence (2) and  $\delta_n$  are well defined, and  $x_n$  converges to  $x^*$  with order of convergence at least equal to p, i.e., there exists an  $A_0 \le 1$  such that  $\|x_n - x^*\| \le \|x_0 - x^*\|$   $A_0 = 1$ .

Proof: For a small U , the sequences exist by Theorem 1.  $\|x_{n+1} - x^*\| = \|x_n - x^* - \Gamma(x_n')[P(x_n) - P(x^*)]\|$   $= \|x_n - x^* - \Gamma(x_n')P'(x_n)(x_n - x^*) + \frac{1}{2}\Gamma(x_n')P''(x_n + \lambda(x^* - x_n'))$   $(x_n - x^*)^2 \|$ 

for some &  $\in$  (0,1). Hence  $\|\mathbf{x}_{n+1} - \mathbf{x}^*\| \le \delta_n \|\mathbf{x}_n - \mathbf{x}^*\| + \mathbf{M} \|\mathbf{x}_n - \mathbf{x}^*\|^2$  where  $\mathbf{M} = \frac{1}{2} \ \mathbf{K}_1 \ \mathbf{K}_2$ ; for convenience write  $\mathbf{e}_n = \|\mathbf{x}_n - \mathbf{x}^*\|$ , so  $\mathbf{e}_{n+1} \le \delta_n \mathbf{e}_n + \mathbf{M}\mathbf{e}_n^2$ . By choosing  $\mathbf{U}$  smaller if necessary, we can assume  $\mathbf{e}_0 < 1$ ,  $\delta_0 + \mathbf{M}\mathbf{e}_0 < 1$ ; hence  $\mathbf{e}_n < 1$ ,  $\delta_n + \mathbf{M}\mathbf{e}_n < 1$  for all n. Therefore  $\mathbf{e}_{n+1} \le \delta_n \mathbf{e}_n + \mathbf{M}\mathbf{e}_n^p \equiv \mathbf{A}_n \mathbf{e}_n$ ,  $\mathbf{A}_n \equiv \delta_n + \mathbf{M}\mathbf{e}_n^{p-1}$ .  $\mathbf{A}_{n+1} = \delta_{n+1} + \mathbf{M}\mathbf{e}_{n+1}^{p-1} \le \delta_n^p + \mathbf{M}[\mathbf{A}_n \mathbf{e}_n]^{p-1} = \delta_n^p + \mathbf{A}_n^{p-1} \mathbf{M}\mathbf{e}_n^{p-1} = \delta_n^p + \mathbf{A}_n^{p-1} (\mathbf{A}_n - \delta_n) = \delta_n^p - \mathbf{A}_n^{p-1} \delta_n + \mathbf{A}_n^p$ . Now  $\delta_n \le \mathbf{A}_n \Longrightarrow -\mathbf{A}_n^{p-1} \le -\delta_n^{p-1} \Longrightarrow \mathbf{A}_{n+1} \le \delta_n^p - \delta_n^{p-1} \delta_n + \mathbf{A}_n^p = \mathbf{A}_n^p$ , and hence  $\mathbf{A}_n \le \mathbf{A}_0^{p^n}$ . It follows that  $\mathbf{e}_n \le \mathbf{e}_0 \mathbf{A}_0^{p^{n+1}-1}$ . Q.E.D.

If  $\Gamma$  (x) is a left inverse of  $P^{\bullet}(x)$  and  $x_n^{\bullet}=x_n^{\bullet}$ , then  $\delta_n=0$  and the above theorem states that, asymptotically, quadratic convergence occurs.
