#### Abstract

The problem of approximating smooth $L_{p}$-functions from spaces spanned by the integer translates of a radially symmetric function $\phi$ is very well understood. In case the points of translation $\Gamma \Xi \Gamma$ are scattered throughout $\mathbb{R}^{d} \Gamma$ the approximation problem is only well understood in the "stationary" setting. In this work $\Gamma$ we provide lower bounds on the obtainable approximation orders in the "non-stationary" setting under the assumption that $\Xi$ is a small perturbation of $\mathbb{Z}^{d}$. The functions which we can approximate belong to certain Besov spaces. Our results $\Gamma$ which are similar in many respects to the known results for the case $\Xi=\mathbb{Z}^{d}$ 「apply specifically to the examples of the Gauss kernel and the Generalized Multiquadric.

## 1. Introduction

Let $C\left(\mathbb{R}^{d}\right)$ denote the collection of all continuous functions $f: \mathbb{R}^{d} \rightarrow \mathbb{C}$ equipped with the topology of uniform convergence on compact sets. For $\phi \in C\left(\mathbb{R}^{d}\right) \Gamma$ and $\Xi \subset$ $\mathbb{R}^{d} \Gamma$ we define $S_{0}(\phi ; \Xi):=\operatorname{span}\{\phi(\cdot-\xi): \xi \in \Xi\}$, and we let $S(\phi ; \Xi)$ denote the closure of $S_{0}(\phi ; \Xi)$ in $C\left(\mathbb{R}^{d}\right)$. The area of Radial Basis Functions has as its motivation the problem of approximating a smooth function $f: \mathbb{R}^{d} \rightarrow \mathbb{C}$ from $S(\phi ; \Xi)$ given only the information $f_{\mid \equiv}$. The area gets its name from the fact that most of the commonly used functions $\phi$ are radially symmetric. Three important examples are the Polyharmonic Spline $\Gamma$

$$
\phi(x):= \begin{cases}|x|^{\gamma-d}, & \text { if } \gamma-d \in(0 \ldots \infty) \backslash 2 \mathbb{N}, \\ |x|^{\gamma-d} \log (|x|), & \text { if } \gamma-d \in 2 \mathbb{N},\end{cases}
$$

the Gauss kernel $\Gamma \phi(x):=e^{-|x|^{2} / 4}$, and the Generalized Multiquadric $\Gamma$

$$
\phi(x):= \begin{cases}\left(1+|x|^{2}\right)^{\left(\gamma_{0}-d\right) / 2}, & \text { if } \gamma_{0}-d \in(-d \ldots \infty) \backslash 2 \mathbb{Z}_{+}, \\ \left(1+|x|^{2}\right)^{\left(\gamma_{0}-d\right) / 2} \log \left(1+|x|^{2}\right), & \text { if } \gamma_{0}-d \in 2 \mathbb{Z}_{+} .\end{cases}
$$

Here $\Gamma \mathbb{N}:=\{1,2,3, \ldots\}$ and $\mathbb{Z}_{+}:=\{0,1,2, \ldots\}$. The area of Radial Basis Functions encompasses many practical as well as theoretical issues; for a recent survey the reader is referred to $[8]$ (see also [12] $[22]$ ). In this paper we are concerned only with the issue of approximation.

Jackson and Buhmann made the simplifying assumption $\Xi=\mathbb{Z}^{d}$ in their initial investigations (cf. $[17] \Gamma[6] \Gamma[7]$ ). These initial investigations were followed by others working also under the assumption $\Xi=\mathbb{Z}^{d}$ (namely $\left.\Gamma[13] \Gamma[9] \Gamma[5] \Gamma[2] \Gamma[4] \Gamma[23] \Gamma[18] \Gamma[19]\right)$ until the simplified problem was very well understood. In order to describe these results $\Gamma$ we need a few more definitions. The space $S(\phi ; \Xi)$ can be refined by dilation obtaining

$$
S^{h}(\phi ; \Xi):=\{s(\cdot / h): s \in S(\phi ; \Xi)\}
$$

Or in other words $\Gamma S^{h}(\phi ; \Xi)$ is the closure $\Gamma$ in $C\left(\mathbb{R}^{d}\right) \Gamma$ of the span of the $h \Xi$-translates of $\phi(\cdot / h)$. It is hoped that a smooth function $f$ can be approximated better and better from $S^{h}(\phi ; \Xi)$ as $h \rightarrow 0$. In the literature Ithis is usually quantified by notions of approximation
order. The essential requirement in the statement " $\left(S^{h}(\phi ; \Xi)\right)_{h}$ provides $L_{p^{\prime}}$-approximation of order $\gamma^{\prime \prime}$ is that

$$
\operatorname{dist}\left(f, S^{h}(\phi ; \Xi) ; L_{p}\right)=O\left(h^{\gamma}\right), \quad \text { as } h \rightarrow 0
$$

for all sufficiently smooth $f \in L_{p}:=L_{p}\left(\mathbb{R}^{d}\right) \Gamma$ where

$$
\operatorname{dist}(f, A ; X):=\inf _{a \in A}\|f-a\|_{X}
$$

The notion of 'sufficiently smooth' should at least include all compactly supported $C^{\infty}$ functions. We describe now two of the major themes which developed from the above mentioned works. First $\Gamma$ if $\widehat{\phi} \Gamma$ the Fourier transform of $\phi \Gamma$ looks like $|\cdot|^{-\gamma}$ near $0 \Gamma$ then under various ( $p$-dependent) side conditions it was shown that the ladder $\left(S^{h}\left(\phi ; \mathbb{Z}^{d}\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma \Gamma 1 \leq p \leq \infty$. Typical examples here would be the Polyharmonic Spline and the Generalized Multiquadric ( $\gamma:=\gamma_{0}$ ).

The ladder $\left(S^{h}(\phi ; \Xi)\right)_{h}$ is known as a stationary ladder because it is obtained by dilating the same space $S(\phi ; \Xi)$. More generally we may use $\Gamma$ as the $h$-entry of our ladder $\Gamma$ the $h$ dilate of an $h$-dependent space $S\left(\phi_{h} ; \Xi\right)$ to obtain a non-stationary ladder $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$. It is in this more general setting that the second theme was developed. Starting with a very smooth function $\phi \Gamma$ define $\phi_{h}:=\phi(\kappa(h) \cdot)$ for some function $\kappa:(0 \ldots 1] \rightarrow(0 \ldots \infty)$ which decays to 0 as $h \rightarrow 0$. If $\widehat{\phi}$ decays exponentially at $\infty \Gamma$ then it could sometimes be shown that the non-stationary ladder $\left(S^{h}\left(\phi_{h} ; \mathbb{Z}^{d}\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma$ provided that $\kappa(h)$ decays to 0 sufficiently fast with $h$. Typical examples here are the Gauss kernel and the Generalized Multiquadric. Although arbitrarily high approximation orders can be obtained if $\kappa(h)$ decays sufficiently fast (see $[24] \Gamma[26] \Gamma[20]$ where $\kappa(h)=O(h)) \Gamma$ there is a price to be paid in terms of numerical stability as $\kappa(h)$ decreases. Thus $\Gamma$ for practical reasons $\Gamma$ it is desirable to know $\Gamma$ for a given $\gamma \Gamma$ the slowest decaying $\kappa$ which still yields $L_{p}$-approximation of order $\gamma$. For the example of the Gauss kernelГBeatson and Light [2] have shown that if

$$
\lim _{h \rightarrow 0} \kappa(h)^{2} \log (1 / h)=\frac{(2 \pi)^{2}}{\gamma}
$$

then the non-stationary ladder $\left(S^{h}\left(\phi_{h} ; \mathbb{Z}^{d}\right)\right)_{h}$ almost provides $L_{\infty}$-approximation of order $\gamma$ (their error looks like $h^{\gamma}$ times some power of $|\log h|$ ). It is now known (cf. [18] [ [19]) that $\left(S^{h}\left(\phi_{h} ; \mathbb{Z}^{d}\right)\right)_{h}$ provides $L_{p}$-approximation of order (exactly) $\gamma$ for all $1 \leq p \leq \infty$ (see also $[5](p=\infty) \Gamma[4](p=2))$.

Recently $\Gamma$ there have been a few successful adaptations of some of the abovementioned techniques (i.e. $\Gamma$ those stationary techniques associated with the first theme) to the more general setting where $\Xi$ is allowed to be scattered throughout $\mathbb{R}^{d}$. Buhmann $\Gamma$ Dyn $\Gamma$ and Levin [10] have shown that if $\widehat{\phi} \sim|\cdot|^{-2 m}$ near $0 \Gamma$ for some $m \in \mathbb{N} \Gamma$ if certain other side conditions are satisfied $\Gamma$ and if $\Xi$ satisfies a mild restriction $\Gamma$ then the stationary ladder $\left(S^{h}(\phi ; \Xi)\right)_{h}$ almost provides $L_{\infty}$-approximation of order $2 m$ (their error looks like $\left.O\left(h^{2 m}|\log h|\right)\right)$. Moreover $\Gamma$ this approximation is realized by an explicit scheme which a at the $h$ levelГuses only the information $f_{\left.\right|^{2} \Xi}$. The mild restriction on $\Xi$ is that there should exist $C_{0}<\infty$ such that every ball of radius $C_{0}$ contains an element of $\Xi$.

Dyn and Ron [14] generalized the results of [10]. They showed that if one has in hand a specific scheme for approximating from the stationary ladder $\left(S^{h}\left(\phi ; \mathbb{Z}^{d}\right)\right)_{h} \Gamma$ then this
scheme can be converted into a scheme for approximation from the ladder $\left(S^{h}(\phi ; \Xi)\right)_{h}$. Under certain circumstances $\Gamma$ it was shown that the latter scheme provides $L_{\infty}$-approximation of order $\gamma$ if the former did. Their results apply primarily to functions $\phi$ for which $\widehat{\phi} \sim|\cdot|^{-k}$ near 0 for some $k \geq \gamma$. In particularГit was shown that the results of [10] could be obtained by converting the stationary schemes detailed in the paper [13] into the scheme of [10] via a variant of the general conversion method of [14]. Following [14] [Buhmann and Ron [11] extended the results of [14] to $L_{p}$-approximation for $p$ in the range $1 \leq p \leq \infty$.

The present work is primarily concerned with providing lower bounds on the $L_{p^{-}}$ approximation order $(1 \leq p \leq \infty)$ of a given non-stationary ladder $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$. Our results begin with the observation that $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ being able to approximate to order $O\left(h^{\gamma}\right)$ the $\mathbb{Z}^{d}$-translates of a certain very nice function $\eta \Gamma$ in a certain collective sense $\Gamma$ implies that $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma$ for all $1 \leq p \leq \infty$ (see the beginning of Section 5). This is reminiscent of the approach taken in [14] where the $\mathbb{Z}^{d}$-translates of $\phi$ were approximated from the space $S(\phi ; \Xi)$. Due to the niceness of $\eta \Gamma$ the problem of approximating the shifts of $\eta$ is fairly tractable if $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d} \Gamma$ that is $\Gamma$ if

$$
\boldsymbol{\delta}(\Xi):=\inf \left\{\delta>0: \mathbb{Z}^{d} \subset \Xi+\delta Q\right\}
$$

is sufficiently small. Here $Q:=(-1 / 2 \ldots 1 / 2)^{d}$ is the open unit cube in $\mathbb{R}^{d}$. We point out that our ability to approximate the shifts of $\eta$ from $S^{h}\left(\phi_{h} ; \Xi\right)$ does not require $S\left(\phi_{h} ; \mathbb{Z}^{d}\right)$ to contain any polynomials; this is in stark contrast to the situation in [14] where the ability to approximate the shifts of $\phi$ from $S(\phi ; \Xi)$ is closely related to the polynomials contained in $S\left(\phi ; \mathbb{Z}^{d}\right)$. We are subsequently able to identify sufficient conditions which ensure that $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma$ for all $1 \leq p \leq \infty$. These sufficient conditions do not assume the family $\left(\phi_{h}\right)_{h}$ to be radially symmetric. However $\Gamma$ we have made considerable effort in specializing our sufficient conditions to the case where the family $\left(\phi_{h}\right)_{h}$ is obtained by dilating a fixed radially symmetric function $\phi \Gamma$ namely $\Gamma$ $\phi_{h}:=\phi(\kappa(h) \cdot)$ where $\kappa:(0 \ldots 1] \rightarrow(0 \ldots \infty)$ is as described above. These specialized results apply in particular to the examples where $\phi$ is the Gauss kernel or the Generalized Multiquadric. For the Gauss kernel we show that if

$$
\limsup _{h \rightarrow 0} \kappa(h)^{2} \log (1 / h)<\frac{\pi^{2}}{\gamma}, \quad \text { for some } \gamma \in(0 \ldots \infty)
$$

and if $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d} \Gamma$ then the non-stationary ladder $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma$ for all $1 \leq p \leq \infty$. For the Generalized Multiquadric「we show that if

$$
\underset{h \rightarrow 0}{\limsup } \kappa(h) \log (1 / h)<\frac{\pi}{\gamma_{1}}, \quad \text { for some } \gamma_{1} \in(0 \ldots \infty)
$$

and if $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d} \Gamma$ then the non-stationary ladder $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of of order $\gamma_{0}+\gamma_{1}$ for all $1 \leq p \leq \infty$.

We have also specialized our general sufficient conditions to the non-stationary scenario where $\phi_{h}:=\phi\left(h^{\theta} \cdot\right)(0<\theta \leq 1)$ and $\phi$ is a continuous radially symmetric function satisfying $\left.|\cdot|\right|^{d+1} \phi \in L_{1} \Gamma|\widehat{\phi}(x)| \sim(1+|x|)^{-\gamma} \Gamma$ and $\left|\lambda^{(k)}(\rho)\right|=O\left(\rho^{-\gamma-k}\right)$ as $\rho \rightarrow \infty \Gamma 0 \leq k \leq d+1 \Gamma$
where $\lambda$ is defined by $\widehat{\phi}(x)=\lambda(|x|)$. We show that if $\gamma>d$ and $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d}$ Гthen the non-stationary ladder $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\theta \gamma$ for all $1 \leq p \leq \infty$.

An outline of the sequel is as follows:
In $\S 2 \Gamma$ we give our precise definition of $L_{p}$-approximation order. The results mentioned above $\Gamma$ which specialize our general result to the case $\phi_{h}:=\phi(\kappa(h) \cdot)$ for a fixed radially symmetric function $\phi$ Гare stated in $\S 3$ and applied to the examples of Polyharmonic Splines $\Gamma$ the Gauss kernel「and the Generalized Multiquadric. The proofs of these specialized results are postponed until $\S 6$ and $\S 7$. Our general results are stated and proved in $\S 5$ while a number of related technical lemmata are gathered into §4.

The following notations are used throughout this work. The natural numbers are denoted by $\mathbb{N}:=\{1,2,3, \ldots\} \Gamma$ while the non-negative integers are denoted by $\mathbb{Z}_{+}:=$ $\{0,1,2, \ldots\}$. For $x \in \mathbb{R}^{d} \Gamma$ we define $|x|:=\sqrt{x_{1}^{2}+\cdots+x_{d}^{2}} \Gamma$ while for multi-indices $\alpha \in \mathbb{Z}_{+}^{d} \Gamma$ we define $|\alpha|:=\left|\alpha_{1}\right|+\cdots+\left|\alpha_{d}\right|$. The open unit cube and the open unit ball in $\mathbb{R}^{d}$ are denoted by $Q:=(-1 / 2 \ldots 1 / 2)^{d}$ and $B:=\left\{x \in \mathbb{R}^{d}:|x|<1\right\} \Gamma$ respectively. For open $\Omega \subseteq \mathbb{R}^{d} \Gamma 1 \leq p \leq \infty \Gamma$ and $m \in \mathbb{Z}_{+} \Gamma$ the Sobolev spaces $W_{p}^{m}(\Omega)$ are defined by

$$
W_{p}^{m}(\Omega):=\left\{f:\|f\|_{W_{p}^{m}(\Omega)}:=\left(\sum_{|\alpha| \leq m}\left\|D^{\alpha} f\right\|_{L_{p}(\Omega)}^{p}\right)^{1 / p}<\infty\right\}
$$

with the usual modification when $p=\infty$. The space of polynomials of total degree at most $k$ is denoted $\Pi_{k}$. The semi-discrete convolution is defined formally by

$$
\phi *_{h}^{\prime} c:=\sum_{j \in \mathbb{Z}^{d}} c(h j) \phi(\cdot / h-j), \quad h>0 .
$$

For $f \in L_{1}:=L_{1}\left(\mathbb{R}^{d}\right) \Gamma$ we denote its Fourier transform by $\widehat{f}(x):=\int_{\mathbb{R}^{d}} e_{-x}(t) f(t) d t$, where $e_{x}$ denotes the complex exponential given by $e_{x}(t):=e^{i x \cdot t}$. The inverse Fourier transform of $f$ is denoted $f^{\vee}$. The collection of compactly supported $C^{\infty}\left(\mathbb{R}^{d}\right)$ functions is denoted by $\mathcal{D}$ and their Fourier transforms by $\widehat{\mathcal{D}}$. Moreover $\Gamma \mathcal{D}(\Omega)$ denotes the set of all functions in $\mathcal{D}$ whose support is contained in $\Omega$. All derivatives and supports of functions are to be understood as distributional. We employ the convention that 0 times anything is 0 ; in particular $\Gamma 0 / 0:=0$. We use the symbol const to denote generic constants $\Gamma$ always understood to be a real value in the interval $(0 \ldots \infty)$ that depends only on its specified arguments. Further $\Gamma$ the value of const may change with each occurrence. When using the scaling parameter $h \Gamma$ as in $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h} \Gamma$ it is assumed without further mention that $h \in\left(0 \ldots h_{0}\right]$ for some $h_{0} \in(0 \ldots 1]$. Lastly $\Gamma$ we employ the standard notation $\lceil t\rceil$ to denote the least integer which is $\geq t$.

## 2. Preliminaries

In order to make precise the notion $\Gamma$ " $L_{p}$-approximation of order $\gamma$ " $\Gamma$ we need to specify which functions $f \in L_{p}$ are sufficiently smooth. This will be the Besov space $B_{p}^{\gamma, 1}$ which we now define. Let $\eta \in \widehat{\mathcal{D}}$ satisfy $\widehat{\eta}=1$ on a neighborhood of the origin $\Gamma$ and for $f \in L_{p} \Gamma$
define

$$
f_{k}:= \begin{cases}(\widehat{\eta}(2 \cdot) \hat{f})^{\vee}, & \text { if } k=0  \tag{2.1}\\ \left(\left(\widehat{\eta}\left(2^{1-k} \cdot\right)-\widehat{\eta}\left(2^{2-k} \cdot\right)\right) \widehat{f}\right)^{\vee}, & \text { if } k>0 .\end{cases}
$$

For $1 \leq p \leq \infty \Gamma \gamma \geq 0 \Gamma 1 \leq q \leq \infty \Gamma$ the Besov space $B_{p}^{\gamma, q}$ (see [21]) can be defined as the collection of all tempered distributions $f$ for which

$$
\|f\|_{B_{p}^{\gamma, q}}:=\left\|k \mapsto 2^{\gamma k}\right\| f_{k}\left\|_{L_{p}}\right\|_{\ell_{q}\left(\mathbb{Z}_{+}\right)}<\infty .
$$

It is known (cf. [21]) that $B_{p}^{\gamma, q}$ is a Banach space $\Gamma$ and as $\operatorname{such} \Gamma$ is independent of the choice of $\eta$ (i.e. different choices of $\eta$ yield equivalent norms). We mention the following continuous embeddings (cf. [21]; p. 62):

$$
\begin{aligned}
& B_{p}^{\gamma, q} \hookrightarrow B_{p}^{\gamma_{1}, q_{1}}, \quad \text { if } \gamma_{1}<\gamma \text { or } \gamma_{1}=\gamma, q_{1} \geq q ; \\
& B_{p}^{k, 1} \hookrightarrow W_{p}^{k}\left(\mathbb{R}^{d}\right) \hookrightarrow B_{p}^{k, \infty}, \quad \text { if } k \in \mathbb{Z}_{+} \\
& B_{p}^{\gamma, 1} \hookrightarrow \mathcal{H}_{p}^{\gamma} \hookrightarrow B_{p}^{\gamma, \infty}, \quad \text { if } 1<p<\infty
\end{aligned}
$$

where $\mathcal{H}_{p}^{\gamma}$ is the potential space normed by

$$
\|f\|_{\mathcal{H}_{p}^{\gamma}}:=\left\|\left(\left(1+|\cdot|^{2}\right)^{\gamma / 2} \widehat{f}\right)^{\vee}\right\|_{L_{p}}, \quad \gamma \geq 0,1<p<\infty .
$$

Incidentally $\Gamma$ the function $\eta$ here is the same as that mentioned in the introduction.
Definition 2.2. Let $1 \leq p \leq \infty \Gamma$ let $\Xi \subset \mathbb{R}^{d} \Gamma$ and let $\left(\phi_{h}\right)_{h \in\left(0 . . h_{0}\right]}$ be a family in $C\left(\mathbb{R}^{d}\right)$. We say that the ladder $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma>0$ if there exists $c<\infty$ such that

$$
\operatorname{dist}\left(f, S^{h}\left(\phi_{h} ; \Xi\right) ; L_{p}\right) \leq c h^{\gamma}\|f\|_{B_{p}^{\gamma, 1}}, \quad \forall h \in\left(0 \ldots h_{0}\right], f \in B_{p}^{\gamma, 1}
$$

We mention that it is easy to derive from Definition 2.2 that if $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma$ and if $0<\gamma^{\prime}<\gamma \Gamma$ then

$$
\operatorname{dist}\left(f, S^{h}\left(\phi_{h} ; \Xi\right) ; L_{p}\right) \leq c^{\prime} h^{\gamma^{\prime}}\|f\|_{B_{p}^{\gamma^{\prime}, \infty}}, \quad \forall h \in\left(0 \ldots h_{0}\right], f \in B_{p}^{\gamma^{\prime}, \infty}
$$

Moreover $\operatorname{If} \gamma^{\prime}=\gamma$ Then the same inequality holds provided we replace $h^{\gamma^{\prime}}$ with $h^{\gamma} \log (2 / h)$.

## 3. The Radially Symmetric Case

Our most general result is Theorem 5.8. There $\Gamma$ it is not assumed that the functions $\left(\phi_{h}\right)_{h \in\left(0 . . h_{0}\right]}$ are radially symmetric. However $\Gamma$ the theorem is a bit difficult to read due to its generality. The assumption of radial symmetry turns out to be a convenient means of reducing the complexity of the theorem. In what follows 1 we assume that the functions $\phi_{h}$ are all obtained from a single radially symmetric function $\phi$ by dilation. The abstract conditions of Theorem 5.8 can then be replaced by other easily verifiable conditions on a certain univariate function related to $\widehat{\phi}$. Here are the details:

Theorem 3.1. Let $\phi \in C\left(\mathbb{R}^{d}\right)$ be a radially symmetric function with at most polynomial growth at $\infty$, and assume that $\widehat{\phi}$ can be identified on $\mathbb{R}^{d} \backslash 0$ with $|\cdot|^{-\gamma_{0}} \lambda(|\cdot|)$ for some $\gamma_{0} \in[0 \ldots \infty)$ and $\lambda \in C([0 \ldots \infty))$ with $\lambda(0) \neq 0$. Define

$$
\begin{aligned}
& \bar{\mu}:=\sup \left\{\mu \leq \gamma_{0}:|\phi(x)|=O\left(|x|^{\gamma_{0}-\mu}\right) \text { as }|x| \rightarrow \infty\right\} ; \\
& m:=d+\left\lceil\gamma_{0}-\bar{\mu}\right\rceil,
\end{aligned}
$$

and assume that
(i) $\quad|\phi(x)|=o(1) \quad a s|x| \rightarrow \infty \quad$ if $\gamma_{0}=0$;
(ii) $\quad \gamma_{0}>\left\lceil\gamma_{0}-\bar{\mu}\right\rceil$ if $\gamma_{0}>0$;
(iii) $\lambda \in C^{m}(0 \ldots \infty) \bigcap C^{d+1}(0 \ldots \infty)$;
(iv) $\quad\left|\lambda^{(k)}(\rho)\right|=O\left(\rho^{\varepsilon-k}\right)$ as $\rho \rightarrow 0, \quad \forall 1 \leq k \leq m$;
(v) $\quad\left|\lambda^{(k)}(\rho)\right|=O\left(\rho^{\gamma_{0}-d-\varepsilon}\right)$ as $\rho \rightarrow \infty, \quad \forall 0 \leq k \leq d+1$,
for some $\varepsilon \in(0 \ldots 1)$. If $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d}$, then the stationary ladder $\left(S^{h}(\phi ; \Xi)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma_{0}$ for all $1 \leq p \leq \infty$. If, in addition to the above, there exists $\theta, a, N \in(0 \ldots \infty)$ such that

$$
\begin{equation*}
\sup _{0<\rho<\infty} \frac{\exp \left(-a \rho^{\theta}\right)}{|\lambda(\rho)|}<\infty ; \tag{vi}
\end{equation*}
$$

$$
\begin{equation*}
\left|\lambda^{(k)}(\rho)\right|=O\left(\rho^{N} \exp \left(-\rho^{\theta}\right)\right) \text { as } \rho \rightarrow \infty, \quad \forall 0 \leq k \leq d+1, \tag{vii}
\end{equation*}
$$

and if we define $\phi_{h}:=\phi(\kappa(h) \cdot), h \in(0 \ldots 1]$, for some $\kappa:(0 \ldots 1] \rightarrow(0 \ldots \infty)$ satisfying

$$
\limsup _{h \rightarrow 0} \kappa(h)^{\theta} \log (1 / h)<\frac{\pi^{\theta}}{\gamma_{1}}, \quad \text { for some } \gamma_{1} \in(0 \ldots \infty)
$$

then the non-stationary ladder $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma_{0}+\gamma_{1}$ for all $1 \leq p \leq \infty$ whenever $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d}$.

In order to demonstrate the utility of Theorem 3.1 Twe consider now a few examples.
Example 3.2. Polyharmonic Spline: Let $\gamma>d$ and define $\phi:=|\cdot|^{\gamma-d}$ if $\gamma-d \notin 2 \mathbb{N} \Gamma$ or $\phi:=|\cdot|^{\gamma-d} \log (|\cdot|)$ if $\gamma-d \in 2 \mathbb{N}$. We will show $\Gamma$ as an application of Theorem 3.1Гthat the stationary ladder $\left(S^{h}(\phi ; \Xi)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma$ for all $1 \leq p \leq \infty$ whenever $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d}$.

According to $[16] \Gamma \widehat{\phi}$ can be identified on $\mathbb{R}^{d} \backslash 0$ with $\pm \operatorname{const}(d, \gamma)|\cdot|^{-\gamma}$. So $\Gamma$ in terms of Theorem $3.1 \Gamma \lambda$ is constant $\Gamma \bar{\mu}=d \Gamma$ and $m=\lceil\gamma\rceil$. It is now trivial to verify that conditions (i)-(v) are satisfied (with $\gamma_{0}:=\gamma \Gamma \varepsilon \leq \gamma-d$ ). The desired conclusion now follows from Theorem 3.1.

Example 3.3. Gauss kernel: Let $\phi:=e^{-|x|^{2} / 4} \Gamma$ and let $\kappa:(0 \ldots 1] \rightarrow(0 \ldots \infty)$ satisfy

$$
\limsup _{h \rightarrow 0} \kappa(h)^{2} \log (1 / h)<\frac{\pi^{2}}{\gamma}, \quad \text { for some } \gamma \in(0 \ldots \infty) \text {. }
$$

Define

$$
\phi_{h}(x):=\phi(\kappa(h) x)=e^{-\kappa(h)^{2}|x|^{2} / 4}, \quad x \in \mathbb{R}^{d}, h \in(0 \ldots 1] .
$$

We will show Гas an application of Theorem 3.1 That the non-stationary ladder $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma$ for all $1 \leq p \leq \infty$ whenever $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d}$.

For that note that $\widehat{\phi}(x)=(4 \pi)^{d / 2} e^{-|x|^{2}}$. Hence we fall into the hypothesis of Theorem 3.1 with $\gamma_{0}=\bar{\mu}=0 \Gamma m=d \Gamma$ and $\lambda(\rho)=(4 \pi)^{d / 2} e^{-\rho^{2}}$. That conditions (i)-(v) hold is fairly obvious. Condition (vi) holds with $\theta:=2$ and $a:=1$. Since $\lambda^{(k)} \in \lambda \Pi_{k} \Gamma$ it is easy to see that condition (vii) is satisfied with $N:=d+1$. The desired conclusion now follows from Theorem 3.1 (with $\gamma_{1}:=\gamma$ ).

Example 3.4. Generalized Multiquadric: Let $\gamma_{0}>0$ and define $\phi:=\left(1+|\cdot|^{2}\right)^{\left(\gamma_{0}-d\right) / 2}$ if $\gamma_{0}-d \notin 2 \mathbb{Z}_{+}$or $\Gamma \phi:=\left(1+|\cdot|^{2}\right)^{\left(\gamma_{0}-d\right) / 2} \log \left(1+|\cdot|^{2}\right)$ if $\gamma_{0}-d \in 2 \mathbb{Z}_{+}$. We will show $\Gamma$ as an application of Theorem $3.1 \Gamma$ that the stationary ladder $\left(S^{h}(\phi ; \Xi)\right)_{h}$ provides $L_{p^{-}}$ approximation of order $\gamma_{0}$ for all $1 \leq p \leq \infty$ whenever $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d}$. Moreover $\Gamma$ if $\kappa:(0 \ldots 1] \rightarrow(0 \ldots \infty)$ satisfies

$$
\limsup _{h \rightarrow 0} \kappa(h) \log (1 / h)<\frac{\pi}{\gamma_{1}}, \quad \text { for some } \gamma_{1} \in(0 \ldots \infty),
$$

and if $\phi_{h}:=\phi(\kappa(h) \cdot) \Gamma \forall h \in(0 \ldots 1] \Gamma$ then the non-stationary ladder $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of of order $\gamma_{0}+\gamma_{1}$ for all $1 \leq p \leq \infty$ whenever $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d}$.

For this we note that according to $[16] \Gamma \widehat{\phi}$ can be identified on $\mathbb{R}^{d} \backslash 0$ with $b|\cdot|^{-\gamma_{0} / 2} K_{\gamma_{0} / 2}(|\cdot|) \Gamma$ where $K_{\nu}$ is the modified Bessel function of order $\nu$ (see [1]) and $b=b\left(d, \gamma_{0}\right)$ is some nonzero constant. One obtains from [1] that for $\nu>0 \Gamma$

$$
K_{\nu}(\rho)=\rho^{-\nu} A_{1}\left(\rho^{2}\right)+\rho^{\nu} A_{2}\left(\rho^{2}\right)+\rho^{\nu} \log (\rho) A_{3}\left(\rho^{2}\right), \quad \rho>0,
$$

where $A_{1} \Gamma A_{2} \Gamma A_{3}$ are entire and $A_{1}(0) \neq 0$. Actually $\Gamma A_{3} \neq 0$ only when $\nu \in \mathbb{N}$. So $\Gamma$ in terms of Theorem 3.1Г

$$
\begin{equation*}
b^{-1} \lambda(\rho)=\rho^{\gamma_{0} / 2} K_{\gamma_{0} / 2}(\rho)=A_{1}\left(\rho^{2}\right)+\rho^{\gamma_{0}} A_{2}\left(\rho^{2}\right)+\rho^{\gamma_{0}} \log (\rho) A_{3}\left(\rho^{2}\right), \quad \rho \geq 0 \tag{3.5}
\end{equation*}
$$

Note that $\lambda(0) \neq 0 \Gamma \lambda \in C([0 \ldots \infty)) \cap C^{\infty}((0 \ldots \infty)) \Gamma$ and $\bar{\mu}=\min \left\{\gamma_{0}, d\right\}$. Hence (i) $\Gamma(i i) \Gamma$ and (iii) of Theorem 3.1 hold. If $0<\varepsilon<\min \left\{1, \gamma_{0}\right\}$ Then (iv) follows easily from (3.5). We turn now to conditions (v)-(vii). For this we employ the following integral representation of $K_{\nu}$ (see [1]). If $\nu>0 \Gamma$ then

$$
K_{\nu}(\rho)=\operatorname{const}(\nu) \rho^{\nu} \int_{1}^{\infty} e^{-\rho t}\left(t^{2}-1\right)^{\nu-\frac{1}{2}} d t, \quad \rho>0 .
$$

Hence $\Gamma$

$$
\begin{equation*}
\lambda(\rho)= \pm \operatorname{const}\left(d, \gamma_{0}\right) \rho^{\gamma_{0}} \int_{1}^{\infty} e^{-\rho t}\left(t^{2}-1\right)^{\frac{\gamma_{0}-1}{2}} d t, \quad \rho>0 \tag{3.6}
\end{equation*}
$$

Note that $|\lambda(\rho)|>0$ for all $\rho \in[0 \ldots \infty)$. Put $\theta:=1$. Now if $a>1 \Gamma$ then

$$
\begin{aligned}
& \frac{|\lambda(\rho)|}{\exp (-a \rho)}=\operatorname{const}\left(d, \gamma_{0}\right) \rho^{\gamma_{0}} \int_{1}^{\infty} e^{-\rho(t-a)}\left(t^{2}-1\right)^{\frac{\gamma_{0}-1}{2}} d t \\
& \geq \operatorname{const}\left(d, \gamma_{0}\right) \rho^{\gamma_{0}} \int_{1}^{a} e^{\rho(a-t)}\left(t^{2}-1\right)^{\frac{\gamma_{0}-1}{2}} d t \nearrow \infty \quad \text { as } \rho \nearrow \infty
\end{aligned}
$$

which proves (vi). Now $\Gamma$ due to the exponential decay of the integrand in (3.6) when $\rho>0 \Gamma$ it is a straightforward matter to verify that

$$
\frac{d^{k}}{d \rho^{k}} \int_{1}^{\infty} e^{-\rho t}\left(t^{2}-1\right)^{\frac{\gamma_{0}-1}{2}} d t=\int_{1}^{\infty} \frac{d^{k}}{d \rho^{k}} e^{-\rho t}\left(t^{2}-1\right)^{\frac{\gamma_{0}-1}{2}} d t, \quad k \in \mathbb{Z}_{+}
$$

Hence $\Gamma$

$$
\begin{aligned}
& \frac{\lambda^{(k)}(\rho)}{\operatorname{const}\left(d, \gamma_{0}\right)} \\
& = \pm \sum_{j=0}^{k}\binom{k}{j} \gamma_{0}\left(\gamma_{0}-1\right) \cdots\left(\gamma_{0}-(k-j-1)\right) \rho^{\gamma_{0}-(k-j)} \int_{1}^{\infty}(-t)^{j} e^{-\rho t}\left(t^{2}-1\right)^{\frac{\gamma_{0}-1}{2}} d t .
\end{aligned}
$$

Thus $\Gamma$ for $\rho>1 \Gamma$

$$
\begin{aligned}
& \left|\lambda^{(k)}(\rho)\right| \leq \operatorname{const}\left(d, \gamma_{0}, k\right) \rho^{\gamma_{0}} \int_{1}^{\infty} t^{k} e^{-\rho t}\left(t^{2}-1\right)^{\frac{\gamma_{0}-1}{2}} d t \\
& \leq \operatorname{const}\left(d, \gamma_{0}, k\right) \rho^{\gamma_{0}} e^{-\rho} \int_{1}^{\infty} t^{k} e^{1-t}\left(t^{2}-1\right)^{\frac{\gamma_{0}-1}{2}} d t=\operatorname{const}\left(d, \gamma_{0}, k\right) \rho^{\gamma_{0}} e^{-\rho} .
\end{aligned}
$$

Therefore (vii) and (v) hold. The desired conclusion now follows from Theorem 3.1.
Another scenario where Theorem 5.8 can be applied is described in the following result.
Theorem 3.7. Let $\phi \in C\left(\mathbb{R}^{d}\right)$ be a radially symmetric function satisfying $|\cdot|^{d+1} \phi \in L_{1}$. Define $\lambda \in C^{d+1}[0 \ldots \infty)$ by $\widehat{\phi}(x)=\lambda(|x|), x \in \mathbb{R}^{d}$, and assume that for some $\gamma>d$,

$$
\begin{equation*}
\sup _{0 \leq \rho<\infty} \frac{(1+\rho)^{-\gamma}}{|\lambda(\rho)|}<\infty \quad \text { and } \tag{i}
\end{equation*}
$$

$$
\begin{equation*}
\left|\lambda^{(k)}(\rho)\right|=O\left(\rho^{-\gamma-k}\right) \text { as } \rho \rightarrow \infty, \quad \forall 0 \leq k \leq d+1 . \tag{ii}
\end{equation*}
$$

Let $\theta \in(0 . .1]$ and for $h \in(0 . .1]$ define $\phi_{h}:=\phi\left(h^{\theta}.\right)$. If $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d}$, then $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\theta \gamma$ for all $1 \leq$ $p \leq \infty$.

Theorem 3.7 applies $\Gamma$ for example $\Gamma$ to the exponentially decaying function
$\phi=|\cdot|^{(\gamma-d) / 2} K_{(\gamma-d) / 2}(|\cdot|)$ whose Fourier transform is a constant times $\left(1+|\cdot|^{2}\right)^{-\gamma / 2}$. Furthermore [if we multiply this function by a radially symmetric $\sigma \in \mathcal{D} \backslash 0 \Gamma$ then Theorem 3.7 applies to the resultant compactly supported function $\phi=\sigma|\cdot|^{(\gamma-d) / 2} K_{(\gamma-d) / 2}(|\cdot|)$ provided $\sigma$ has a nonnegative Fourier transform. Regarding the applicability of Theorem 3.7 to Wendland's compactly supported radial functions $\phi_{d, k} \Gamma$ it is easy to derive from [25] that for $d$ odd $\Gamma$ if $\gamma$ is chosen to satisfy condition (i) $\Gamma$ then condition (ii) necessarily fails. One expects the same in the case $d$ even $\Gamma$ but this has yet to be proven.

## 4. Some Useful Lemmata

In this section we gather some technical lemmata which will be used in the following section. The following lemma shows that a weighted $\ell_{p}$-norm is dominated by its corresponding weighted $L_{p}$-norm for band-limited functions (with a fixed band).
Lemma 4.1. Let $\rho: \mathbb{R}^{d} \rightarrow[1 \ldots \infty)$ be measurable, have at most polynomial growth at $\infty$, and satisfy

$$
\rho(x+y) \leq \rho(x) \rho(y), \quad \forall x, y \in \mathbb{R}^{d} .
$$

Then, for all $1 \leq p \leq \infty$,

$$
\|\rho f\|_{\ell_{p}\left(\mathbb{Z}^{d}\right)} \leq \operatorname{const}(d, \rho)\|\rho f\|_{L_{p}\left(\mathbb{R}^{d}\right)},
$$

whenever $f \in L_{p}$ and $\operatorname{supp} \hat{f} \subseteq 2 \pi \bar{Q}$.
Proof. cf. [15; Lemma 1].
The following variant of Poisson's summation formula shows how the semi-discrete convolution acts in the Fourier transform domain.
Lemma 4.2. Let $\phi \in \widehat{\mathcal{D}}$, and let $f$ be a tempered distribution such that $\operatorname{supp} \hat{f}$ is compact. Then for all $h>0$,

$$
\left(\phi *_{h}^{\prime} f\right)^{\wedge}=\widehat{\phi}(h \cdot) \sum_{j \in \mathbb{Z}^{d}} \widehat{f}(\cdot-2 \pi j / h) .
$$

Proof. cf. [19; Lemma 5.7].
The following result allows us to work with a non-harmonic Fourier series in a way similar to that of the standard Fourier series provided that the frequencies in our nonharmonic Fourier series are a sufficiently small perturbation of $\mathbb{Z}^{d}$. We state the result in slightly more generality than needed only to suggest a useful formulation of the problem. The context in which we will actually use the lemma is mentioned in the forthcoming remark. We mention that a similar result can be derived from the results of [15].
Lemma 4.3. Let $\zeta \in \widehat{\mathcal{D}}$ satisfy $\sum_{j \in \mathbb{Z}^{d}} \widehat{\zeta}(\cdot+2 \pi j)=1$ (or equivalently, $\zeta(j)=\delta_{0, j}, j \in \mathbb{Z}^{d}$ ). For $\xi \in \mathbb{R}^{d}$, let $\widehat{\zeta}_{\xi}$ be the $2 \pi \mathbb{Z}^{d}$-periodic function defined by

$$
\widehat{\zeta}_{\xi}(x):=\sum_{j \in \mathbb{Z}^{d}} e_{\xi}(x+2 \pi j) \widehat{\zeta}(x+2 \pi j), \quad x \in \mathbb{R}^{d}
$$

Let $\rho: \mathbb{Z}^{d} \rightarrow[1 \ldots \infty)$ have at most polynomial growth and satisfy

$$
\rho(j+k) \leq \rho(j) \rho(k), \quad \forall j, k \in \mathbb{Z}^{d} .
$$

Then there exists $\delta(\zeta, \rho)>0$ such that if $\xi_{j} \in j+\delta \bar{Q}, \forall j \in \mathbb{Z}^{d}$, for some $0<\delta<\delta(\zeta, \rho)$, then there exists a linear mapping $\Lambda: \ell_{\infty} \rightarrow \ell_{\infty}$, depending only on $\zeta$ and $\left(\xi_{j}\right)_{j \in \mathbb{Z}^{d}}$, such that

$$
\begin{align*}
& \|\Lambda a\|_{\ell_{1}} \leq \operatorname{const}(d, \zeta, \delta)\|a\|_{\ell_{1}}, \quad \forall a \in \ell_{1} ;  \tag{1}\\
& \sum_{j \in \mathbb{Z}^{d}}(\Lambda a)(j) \widehat{\zeta}_{-\xi_{j}}(x)=\sum_{j \in \mathbb{Z}^{d}} a(j) e_{-j}(x), \quad \forall x \in \mathbb{R}^{d}, a \in \ell_{1} \tag{2}
\end{align*}
$$

Moreover, if $\omega: \mathbb{Z}^{d} \rightarrow[1 \ldots \infty)$ satisfies

$$
\begin{aligned}
\text { (i) } & \omega(j) \leq \rho(j), \quad \forall j \in \mathbb{Z}^{d} ; \\
\text { (ii) } & \omega(j+k) \leq \omega(j) \omega(k), \quad \forall j, k \in \mathbb{Z}^{d},
\end{aligned}
$$

then for all $1 \leq p \leq \infty$,

$$
\begin{equation*}
\|\omega \Lambda a\|_{\ell_{p}} \leq \operatorname{const}(d, \zeta, \omega, \delta)\|\omega a\|_{\ell_{p}}, \quad \forall a \in \ell_{\infty} \tag{3}
\end{equation*}
$$

Remark 4.4. If $\operatorname{supp} \widehat{\zeta} \subset\left[-\pi-\varepsilon_{1} \ldots \pi+\varepsilon_{1}\right]^{d}$ and $\widehat{\zeta}=1$ on $\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d}$ for some $\varepsilon_{1} \in(0 \ldots \pi) \Gamma$ then $\widehat{\zeta}_{\xi}=e_{\xi}$ on $\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d}$ for all $\xi \in \mathbb{R}^{d}$. Hence it follows from (2) that

$$
\begin{equation*}
\sum_{j \in \mathbb{Z}^{d}}(\Lambda a)(j) e_{-\xi_{j}}(x)=\sum_{j \in \mathbb{Z}^{d}} a(j) e_{-j}(x), \quad \forall x \in\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d}, a \in \ell_{1} \tag{4.5}
\end{equation*}
$$

In proving Lemma 4.3 Twe make essential use of the following well known result.
Lemma 4.6. Let $X$ be a Banach space and let $L: X \rightarrow X$ be a bounded linear operator. If $\|1-L\|<1$, then $L$ is boundedly invertible and

$$
\left\|L^{-1}\right\| \leq \frac{1}{1-\|1-L\|}
$$

where || || denotes the operator norm in $X$.
Proof of Lemma 4.3. For $\delta>0$ Гdefine

$$
N(\delta):=\sum_{j \in \mathbb{Z}^{d}} \rho(j)\left\|\delta_{j, 0}-\zeta(\cdot+j)\right\|_{L_{\infty}(\delta Q)}
$$

Since $\rho$ has at most polynomial growth $\Gamma$ since $\zeta$ decays rapidly (being a member of $\widehat{\mathcal{D}}$ ) $\Gamma$ and since each term in the sum defining $N(\delta)$ decreases to 0 as $\delta \rightarrow 0 \Gamma$ it follows by the Lebesgue Dominated Convergence Theorem that $N(\delta) \rightarrow 0$ as $\delta \rightarrow 0$. Hence $\Gamma$ there exists $\delta(\zeta, \rho)>0$ such that $N(\delta)<1$ whenever $0<\delta<\delta(\zeta, \rho)$. Let $\xi_{j} \in j+\delta \bar{Q} \Gamma j \in \mathbb{Z}^{d}$ for some $0<\delta<\delta(\zeta, \rho)$. Define the linear operator $L: \ell_{\infty} \rightarrow \ell_{\infty}$ by

$$
L a(j):=\sum_{k \in \mathbb{Z}^{d}} a(k) \zeta\left(j-\xi_{k}\right), \quad j \in \mathbb{Z}^{d}
$$

Let $\omega: \mathbb{Z}^{d} \rightarrow\left[1 \ldots \infty\right.$ ) satisfy (i) and (ii). For $1 \leq p \leq \infty \Gamma$ let $X_{p}$ be the Banach space consisting of all sequences $a: \mathbb{Z}^{d} \rightarrow \mathbb{C}$ for which $\|a\|_{X_{p}}:=\|\omega a\|_{\ell_{p}}<\infty$.

Claim. For $1 \leq p \leq \infty \Gamma L$ is a boundedly invertible operator on $X_{p}$ and

$$
\left\|L^{-1} a\right\|_{X_{p}} \leq \operatorname{const}(d, \zeta, \omega, \delta)\|a\|_{X_{p}}, \quad \forall a \in X_{p}
$$

proof. In view of Lemma 4.6 Tand since $N(\delta)<1$ Гit suffices to show that

$$
\begin{equation*}
\|a-L a\|_{X_{p}} \leq N(\delta)\|a\|_{X_{p}}, \quad \forall a \in X_{p} \tag{4.7}
\end{equation*}
$$

If $a \in X_{1}$ Tthen

$$
\begin{aligned}
& \|a-L a\|_{X_{1}} \leq \sum_{j \in \mathbb{Z}^{d}} \omega(j) \sum_{k \in \mathbb{Z}^{d}}|a(k)|\left|\delta_{k, j}-\zeta\left(j-\xi_{k}\right)\right| \\
& =\sum_{k \in \mathbb{Z}^{d}} \omega(k)|a(k)| \sum_{j \in \mathbb{Z}^{d}} \frac{\omega(j)}{\omega(k)}\left|\delta_{k, j}-\zeta\left(j-\xi_{k}\right)\right|, \quad \text { by Fubini's Theorem } \Gamma \\
& =\sum_{k \in \mathbb{Z}^{d}} \omega(k)|a(k)| \sum_{j \in \mathbb{Z}^{d}} \frac{\omega(j+k)}{\omega(k)}\left|\delta_{j, 0}-\zeta\left(j+k-\xi_{k}\right)\right| \\
& \leq \sum_{k \in \mathbb{Z}^{d}} \omega(k)|a(k)| \sum_{j \in \mathbb{Z}^{d}} \omega(j)\left\|\delta_{j, 0}-\zeta(\cdot+j)\right\|_{L_{\infty}(\delta Q)} \leq N(\delta)\|a\|_{X_{1}} \quad \text { by (i). }
\end{aligned}
$$

If $a \in X_{\infty} \Gamma$ then

$$
\begin{aligned}
& \|a-L a\|_{X_{\infty}} \leq \sup _{j \in \mathbb{Z}^{d}} \omega(j) \sum_{k \in \mathbb{Z}^{d}}|a(k)|\left|\delta_{k, j}-\zeta\left(j-\xi_{k}\right)\right| \\
& \leq\|a\|_{X_{\infty}} \sup _{j \in \mathbb{Z}^{d}} \sum_{k \in \mathbb{Z}^{d}} \frac{\omega(j)}{\omega(k)}\left|\delta_{k, j}-\zeta\left(j-\xi_{k}\right)\right| \\
& \leq\|a\|_{X_{\infty}} \sup _{j \in \mathbb{Z}^{d}} \sum_{k \in \mathbb{Z}^{d}} \frac{\omega(j)}{\omega(k+j)}\left\|\delta_{k, 0}-\zeta(\cdot-k)\right\|_{L_{\infty}(\delta Q)} \\
& \leq\|a\|_{X_{\infty}} \sum_{k \in \mathbb{Z}^{d}} \omega(-k)\left\|\delta_{k, 0}-\zeta(\cdot-k)\right\|_{L_{\infty}(\delta Q)} \leq N(\delta)\|a\|_{X_{\infty}} .
\end{aligned}
$$

Having established (4.7) for $p=1$ and $p=\infty$ Гwe then obtain (4.7) for all $1 \leq p \leq \infty$ by interpolation (see [3; Theorem 3.6]).

With the Claim in view for the special case $\omega=1$ and $p=\infty$ Twe define

$$
\Lambda a:=L^{-1} a, \quad a \in \ell_{\infty}
$$

Note that $\Lambda$ is a linear mapping of $\ell_{\infty}$ onto $\ell_{\infty} \Gamma$ and since the definition of $L$ depends only on $\zeta$ and $\left(\xi_{j}\right)_{j \in \mathbb{Z}^{d}} \Gamma$ the same is true of $\Lambda$. Note that (3) follows from the Claim. Note that (1) follows from (3) in the special case $\omega=1$ and $p=1$. We turn now to (2). Let $a \in \ell_{1}$. By (1) $\Gamma \Lambda a \in \ell_{1}$. Define

$$
\psi:=\sum_{j \in \mathbb{Z}^{d}}(\Lambda a)(j) \zeta\left(\cdot-\xi_{j}\right) .
$$

Then since $\Lambda a \in \ell_{1}$ and $\zeta \in L_{1} \Gamma$ it follows that $\psi \in L_{1}$ and

$$
\widehat{\psi}=\widehat{\zeta} \sum_{j \in \mathbb{Z}^{d}}(\Lambda a)(j) e_{-\xi_{j}}
$$

Similarly $\Gamma$ since $a \in \ell_{1} \Gamma$ it follows that $\zeta *^{\prime} a \in L_{1}$ and

$$
\left(\zeta *^{\prime} a\right)^{\wedge}=\widehat{\zeta} \sum_{j \in \mathbb{Z}^{d}} a(j) e_{-j} .
$$

Note that for $j \in \mathbb{Z}^{d} \Gamma$

$$
\psi(j)=\sum_{k \in \mathbb{Z}^{d}}(\Lambda a)(k) \zeta\left(j-\xi_{k}\right)=(L \Lambda a)(j)=a(j)
$$

Therefore

$$
\begin{aligned}
& \widehat{\zeta} \sum_{j \in \mathbb{Z}^{d}} a(j) e_{-j}=\left(\zeta *^{\prime} a\right)^{\wedge}=\left(\zeta *^{\prime} \psi\right)^{\wedge} \\
& =\widehat{\zeta} \sum_{k \in \mathbb{Z}^{d}} \widehat{\psi}(\cdot+2 \pi k), \quad \text { by Lemma } 4.2, \\
& =\widehat{\zeta} \sum_{k \in \mathbb{Z}^{d}} \widehat{\zeta}(\cdot+2 \pi k) \sum_{j \in \mathbb{Z}^{d}}(\Lambda a)(j) e_{-\xi_{j}}(\cdot+2 \pi k)=\widehat{\zeta} \sum_{j \in \mathbb{Z}^{d}}(\Lambda a)(j) \widehat{\zeta}-\xi_{j}
\end{aligned}
$$

since $\Lambda a \in \ell_{1}$. Finally $\Gamma$ we obtain (2) from the requirement $\sum_{j \in \mathbb{Z}^{d}} \widehat{\zeta}(\cdot+2 \pi j)=1$.
When dealing with basis functions $\phi$ which have growth at $\infty$ Гa difficulty which invariably arises is that of identifying functions in $S(\phi ; \Xi)$ by specifying their Fourier transform. The following lemma gives $\Gamma$ under certain assumptions on $\phi \Gamma$ a simple solution to this difficulty. We mention that the set $\left(0 \ldots \gamma_{0}\right] \cup\left\{\gamma_{0}\right\} \Gamma$ appearing below $\Gamma$ equals $\left(0 \ldots \gamma_{0}\right]$ when $\gamma_{0}>0$ and equals $\{0\}$ when $\gamma_{0}=0$.
Lemma 4.8. Let $\phi \in C\left(\mathbb{R}^{d}\right)$ have at most polynomial growth at $\infty$. Assume that $\widehat{\phi}$ can be identified on $\mathbb{R}^{d} \backslash 0$ with $|\cdot|^{-\gamma_{0}} \lambda$, where $\gamma_{0} \geq 0$ and $\lambda: \mathbb{R}^{d} \rightarrow \mathbb{C}$ is locally integrable on $\mathbb{R}^{d}$, continuous on a neighborhood of 0 , and satisfies $\lambda(0) \neq 0$. Assume that there exists $\mu \in\left(0 \ldots \gamma_{0}\right] \cup\left\{\gamma_{0}\right\}$ such that

$$
|\phi(x)|=o\left(|x|^{\gamma_{0}-\mu}\right) \quad a s|x| \rightarrow \infty .
$$

Let $\Xi \subset \mathbb{R}^{d}, b \in \ell_{1}(\Xi)$, and define

$$
\widehat{g}(x):=|x|^{-\gamma_{0}} \lambda(x) \sum_{\xi \in \Xi} b(\xi) e_{-\xi}(x), \quad x \in \mathbb{R}^{d} \backslash 0 .
$$

If $\widehat{g}$ can be identified a.e. as the Fourier transform of a function $g \in L_{1}$, and if

$$
\begin{equation*}
\sum_{\xi \in \Xi}(1+|\xi|)^{\gamma_{0}-\mu}|b(\xi)|<\infty \tag{4.9}
\end{equation*}
$$

then $g=\sum_{\xi \in \Xi} b(\xi) \phi(\cdot-\xi)$.
We remark that under much weaker assumptions than $g \in L_{1} \Gamma$ there is a standard argument which concludes that $g$ and $\sum_{\xi \in \Xi} b(\xi) \phi(\cdot-\xi)$ differ by at most a polynomial.

The strong assumption $g \in L_{1}$ (which will suffice us in the sequel) serves as a simple means of ensuring that the errant polynomial is in fact 0 .
Proof. By (4.9) and since $|\phi(x)|=O\left(|x|^{\gamma_{0}-\mu}\right)$ it follows that the sum

$$
f:=\sum_{\xi \in \Xi} b(\xi) \phi(\cdot-\xi)
$$

converges in the space of tempered distributions. We begin by showing that $\hat{g}=\hat{f}$ on $\mathbb{R}^{d} \backslash 0$. For that let $\psi \in \mathcal{D}$ be such that $\operatorname{supp} \psi \subset \mathbb{R}^{d} \backslash 0$. Then

$$
\begin{aligned}
& \langle\psi, \widehat{g}\rangle=\int_{\text {supp } \psi} \psi(x)|x|^{-\gamma_{0}} \lambda(x) \sum_{\xi \in \Xi} b(\xi) e_{-\xi}(x) d x \\
& =\sum_{\xi \in \Xi} b(\xi) \int_{\operatorname{supp} \psi} \psi(x)|x|^{-\gamma_{0}} \lambda(x) e_{-\xi}(x) d x, \quad \text { since } b \in \ell_{1}(\Xi) \\
& =\sum_{\xi \in \Xi} b(\xi)\langle\widehat{\psi}, \phi(\cdot-\xi)\rangle=\langle\widehat{\psi}, f\rangle=\langle\psi, \widehat{f}\rangle .
\end{aligned}
$$

Therefore $\widehat{g}=\widehat{f}$ on $\mathbb{R}^{d} \backslash 0 \Gamma$ and hence $f-g$ is a polynomial. If $\gamma_{0}=0 \Gamma$ then $\gamma_{0}-\mu=0$ and so by (4.9) $\Gamma|f(x)|=o(1)$ as $|x| \rightarrow \infty$; since $g \in L_{1} \Gamma$ we must have $f=g$. Having dispensed with the case $\gamma_{0}=0 \Gamma$ let us assume that $\gamma_{0}>0$ (which implies $\mu>0$ ). Since $g \in L_{1} \Gamma$ in order to show that $\widehat{f}=\widehat{g}$ (and hence prove the lemma) $\Gamma$ it suffices to show that $\hat{f}$ is regular (i.e. .locally integrable) on some neighborhood of the origin. We will accomplish this by showing that there exists an $\varepsilon_{1}>0 \Gamma F \in L_{1}\left(\varepsilon_{1} B / 2\right) \Gamma$ and a sequence $\left(f_{n}\right)_{n \in \mathbb{N}}$ in $L_{1}$ such that $\widehat{f}_{n} \rightarrow \widehat{f}$ in the space of tempered distributions $\Gamma$ and $\left|\widehat{f}_{n}(x)\right| \leq c F(x)$ for all $x \in \frac{\varepsilon_{1}}{2} B \backslash 0 \Gamma n \in \mathbb{N} \Gamma$ for some $c<\infty$ which does not depend on $n$ or $x$.

There exists $\varepsilon_{1}, c_{1}, c_{2} \in(0 \ldots \infty)$ such that $c_{1} \leq|\lambda(x)| \leq c_{2} \forall x \in \varepsilon_{1} B$. Define $F:=$ $1+|\cdot|^{-d+\mu}$. Note that $F \in L_{1}\left(\varepsilon_{1} B / 2\right)$. Let $\nu \in \widehat{\mathcal{D}}$ be such that $\nu(0)=1 \Gamma \hat{\nu} \geq 0 \Gamma$ and $\operatorname{supp} \widehat{\nu} \subset \varepsilon_{1} B / 2$. For $n \in \mathbb{N} \Gamma$ define

$$
f_{n}:=\sum_{\xi \in \Xi} b(\xi) \nu((\cdot-\xi) / n) \phi(\cdot-\xi)
$$

By (4.9) Гand since $\nu(0)=1$ it follows that $f_{n} \rightarrow f$ in the space of tempered distributions. Therefore $\Gamma \hat{f}_{n} \rightarrow \hat{f}$ in the space of tempered distributions. On the other hand $\Gamma$ since $b \in \ell_{1}(\Xi)$ and $\nu(\cdot / n) \phi \in L_{1}$ Гit follows that $f_{n} \in L_{1}$ and for $x \in \varepsilon_{1} B \backslash 0 \Gamma$

$$
\left.\widehat{f}_{n}(x)=(\nu(\cdot / n) \phi) \nmid x\right) \sum_{\xi \in \Xi} b(\xi) e_{-\xi}(x) .
$$

Note that for $x \in \varepsilon_{1} B \backslash 0 \Gamma\left|\sum_{\xi \in \Xi} b(\xi) e_{-\xi}(x)\right| \leq \frac{\|g\|_{L_{1}}}{c_{1}}|x|^{\gamma_{0}}$. Therefore $\Gamma$

$$
\left|\widehat{f}_{n}(x)\right| \leq \frac{\|g\|_{L_{1}}}{c_{1}}|(\nu(\cdot / n) \phi) \curlyvee(x)||x|^{\gamma_{0}}, \quad \forall x \in \varepsilon_{1} B \backslash 0 .
$$

So $\operatorname{Fin}$ order to establish $\left|f_{n}(x)\right| \leq c F(x) \forall x \in \frac{\varepsilon}{2} B \backslash 0 \Gamma$ and hence prove the lemma $\operatorname{Tit}$ suffices to show that

$$
\begin{equation*}
|(\nu(\cdot / n) \phi) \mathcal{C}(x)| \leq c\left(|x|^{-\gamma_{0}}+|x|^{-d-\gamma_{0}+\mu}\right) \quad \text { for all } x \in \frac{\varepsilon}{2} B \backslash 0 . \tag{4.10}
\end{equation*}
$$

Since $\nu \in \widehat{\mathcal{D}}$ and $\phi$ satisfies $|\phi(x)|=O\left(|x|^{\gamma_{0}-\mu}\right)$ as $|x| \rightarrow \infty \Gamma$ it follows that $\|\nu(\cdot / n) \phi\|_{L_{1}}=$ $O\left(n^{d+\gamma_{0}-\mu}\right)$ as $n \rightarrow \infty$. Using the estimate $|(\nu(\cdot / n) \phi) \mathcal{C}(x)| \leq\|\nu(\cdot / n) \phi\|_{L_{1}}$ Twe thus obtain (4.10) for the case $0<|x| \leq \frac{\varepsilon_{1}}{n}$. For the remaining case $\Gamma \frac{\varepsilon_{1}}{n}<|x| \leq \frac{\varepsilon_{1}}{2} \Gamma$ we have

$$
\begin{aligned}
& |(\nu(\cdot / n) \phi) \uparrow(x)|=(2 \pi)^{-d}\left|\left(n^{d} \widehat{\nu}(n \cdot) * \widehat{\phi}\right)(x)\right| \leq\left\||\cdot|^{-\gamma_{0}} \lambda\right\|_{L_{\infty}\left(x+\frac{\varepsilon_{1}}{2 n} B\right)} \\
& \leq c_{2}\left(|x|-\frac{\varepsilon_{1}}{2 n}\right)^{-\gamma_{0}} \leq c_{2} 2^{\gamma_{0}}|x|^{-\gamma_{0}}
\end{aligned}
$$

## 5. The General Results

The foundation of our approach might well be called approximation by replacement. Since the structure of $S^{h}\left(\phi_{h} ; \Xi\right)$ is irrelevant to this technique $\Gamma$ we will $\Gamma$ for the moment $\Gamma$ simply assume that $\left(S_{h}\right)_{h \in\left(0 . . h_{0}\right]}$ is a family of closed subspaces of $C\left(\mathbb{R}^{d}\right)$ (these will eventually correspond to $S\left(\phi_{h} ; \Xi\right)$ ) and we define as usual

$$
S_{h}^{h}:=\left\{s(\cdot / h): s \in S_{h}\right\}, \quad h \in\left(0 \ldots h_{0}\right] .
$$

Beginning with the observation that if $h=2^{-n} \Gamma$ and $f \in B_{p}^{\gamma, 1} \Gamma$ then

$$
f \approx \sum_{k=0}^{n} \sum_{j \in \mathbb{Z}^{d}} f_{k}\left(2^{-k} j\right) \eta\left(2^{k} \cdot-j\right)
$$

is a good approximation of $f \Gamma$ the idea is to replace each $\eta\left(2^{k} \cdot-j\right)$ with an approximation drawn from $S_{h}^{h}$. In other words $\Gamma$ we seek suitable $q_{k, j} \in S_{h}^{h}$ such that

$$
f \approx \sum_{k=0}^{n} \sum_{j \in \mathbb{Z}^{d}} f_{k}\left(2^{-k} j\right) q_{k, j}
$$

is also a good approximation to $f$. In order to carry the error analysis through $\Gamma$ the issue becomes not so much how well each $\eta\left(2^{k} \cdot-j\right)$ is approximated by $q_{k, j} \Gamma$ but rather how well $\Gamma$ for each $k \Gamma$ the mapping

$$
\ell_{p} \ni c \mapsto \sum_{j \in \mathbb{Z}^{d}} c(j) \eta\left(2^{k} \cdot-j\right) \in L_{p}
$$

is approximated by the mapping

$$
\ell_{p} \ni c \mapsto \sum_{j \in \mathbb{Z}^{d}} c(j) q_{k, j} \in L_{p}
$$

The following definition and lemma provide a simple means for measuring the size of (or closeness of) such mappings.

Definition 5.1. We define $\mathcal{N}$ to be the collection of all sequences $\left(\boldsymbol{f}_{j}\right)_{j \in \mathbb{Z}^{d}}$ in $C\left(\mathbb{R}^{d}\right)$ for which

$$
\begin{aligned}
& \sum_{j \in \mathbb{Z}^{d}}\left\|\boldsymbol{f}_{j}\right\|_{L_{\infty}(K)}<\infty \quad \text { for all compact } K \subset \mathbb{R}^{d}, \text { and } \\
& \|\boldsymbol{f}\|_{\mathcal{N}}:=\max \left\{\sup _{j \in \mathbb{Z}^{d}}\left\|\boldsymbol{f}_{j}\right\|_{L_{1}},\left\|\sum_{j \in \mathbb{Z}^{d}}\left|\boldsymbol{f}_{j}\right|\right\|_{L_{\infty}}\right\}<\infty .
\end{aligned}
$$

For any complex valued function $g$ whose domain contains $\mathbb{Z}^{d} \Gamma$ we define formally

$$
\boldsymbol{f} \cdot g:=\sum_{j \in \mathbb{Z}^{d}} g(j) \boldsymbol{f}_{j} .
$$

Lemma 5.2. Let $f \in \mathcal{N}$. If $c \in \ell_{\infty}$, then the sum $\boldsymbol{f} \cdot \mathrm{c}$ converges unconditionally in $C\left(\mathbb{R}^{d}\right)$. Moreover, for all $1 \leq p \leq \infty$, the mapping $c \mapsto \boldsymbol{f} \cdot c$ is a bounded linear mapping from $\ell_{p}$ into $L_{p}$ and as such its norm does not exceed $\|\boldsymbol{f}\|_{\mathcal{N}}$.
Proof. That the sum $\boldsymbol{f} \cdot \boldsymbol{c}$ converges unconditionally in $C\left(\mathbb{R}^{d}\right)$ whenever $c \in \ell_{\infty}$ is an immediate consequence of the requirement that $\sum_{j \in \mathbb{Z}^{d}}\left\|\boldsymbol{f}_{j}\right\|_{L_{\infty}(K)}<\infty$ for all compact $K \subset \mathbb{R}^{d}$. That the lemma is true for $p=1$ and $p=\infty$ is clear from the definition of the $\mathcal{N}$-norm. We then interpolation to obtain the lemma for all $1 \leq p \leq \infty$ (see [3ГTheorem 3.6]).

We now state the theorem which provides the foundation of our approach.
Theorem 5.3. Let $\left(S_{r}\right)_{r \in\left(0 . . h_{0}\right]}$ be a family of closed subspaces of $C\left(\mathbb{R}^{d}\right)$, and define

$$
S_{r}^{h}:=\left\{s(\cdot / h): s \in S_{r}\right\}, \quad \forall h, r \in\left(0 \ldots h_{0}\right] .
$$

Let $\eta \in \widehat{\mathcal{D}}$ and $\varepsilon \in(0 . .2 \pi)$ be such that $\operatorname{supp} \hat{\eta} \subset \varepsilon Q$ and $\hat{\eta}=1$ on $\frac{1}{2} \varepsilon Q$. Put $\boldsymbol{\eta}_{j}:=\eta(\cdot-j)$, $j \in \mathbb{Z}^{d}$. If there exists $\gamma>0$ such that for some $A<\infty$,

$$
\begin{equation*}
\operatorname{dist}\left(\boldsymbol{\eta},\left(S_{r}^{h}\right)^{\mathbb{Z}^{d}} \cap \mathcal{N} ; \mathcal{N}\right)<A h^{\gamma}, \quad \forall 0<r \leq h \leq h_{0} \tag{5.4}
\end{equation*}
$$

then

$$
\operatorname{dist}\left(f, S_{h}^{h} ; L_{p}\right) \leq(1+\operatorname{const}(d, \gamma) A) h^{\gamma}\|f\|_{B_{p}^{\gamma, 1}}
$$

for all $f \in B_{p}^{\gamma, 1}, 1 \leq p \leq \infty$.
Proof. Without loss of generality assume $h_{0}=1$. Let $\gamma>0$ and assume that (5.4) holds. Let $1 \leq p \leq \infty$. Let $f \in B_{p}^{\gamma, 1} \Gamma$ and let $f_{k}$ be as in $(2.1) \Gamma k \in \mathbb{Z}_{+}$. For $h \in(0 . .1] \Gamma$ let $n:=n(h)$ be the largest integer for which $h 2^{n} \leq 1$. FirstГlet us make three observations:

Claim 5.5. For all $h \in(0 \ldots 1] \Gamma$

$$
\begin{align*}
& f_{k}=\eta *_{h 2^{n-k}}^{\prime} f_{k}, \quad \forall k \in \mathbb{Z}_{+}  \tag{1}\\
& \left(h 2^{n-k}\right)^{d / p}\left\|f_{k}\right\|_{\ell_{p}\left(h 2^{n-k} \mathbb{Z}^{d}\right)} \leq \operatorname{const}(d)\left\|f_{k}\right\|_{L_{p}}, \quad \forall k \in \mathbb{Z}_{+}  \tag{2}\\
& \left\|f-\sum_{k=0}^{n} f_{k}\right\|_{L_{p}} \leq\|f\|_{B_{p}^{\gamma, 1}} h^{\gamma} \tag{3}
\end{align*}
$$

proof. Note that supp $\widehat{f}_{k}$ is compact. Hence $\Gamma$ by Lemma $4.2 \Gamma$

$$
\left(\eta *_{h 2^{n-k}}^{\prime} f_{k}\right)^{\wedge}=\widehat{\eta}\left(h 2^{n-k} \cdot\right) \sum_{j \in \mathbb{Z}^{d}} \widehat{f}_{k}\left(\cdot-2 \pi j /\left(h 2^{n-k}\right)\right) .
$$

By (2.1) $\Gamma \operatorname{supp} \widehat{f}_{k} \subseteq \operatorname{supp} \widehat{\eta}\left(2^{1-k}.\right) \subseteq 2^{k-1} \varepsilon Q \Gamma \forall k \in \mathbb{Z}_{+}$. It is now a straightforward matter to verify that $\widehat{\eta}\left(h 2^{n-k} \cdot\right)$ and $\widehat{f}_{k}\left(\cdot-2 \pi j /\left(h 2^{n-k}\right)\right)$ have disjoint supports whenever $j \in \mathbb{Z}^{d} \backslash 0$ and that $\widehat{\eta}\left(h 2^{n-k}.\right)=1$ on the support of $\widehat{f}_{k}$. Therefore $\Gamma\left(\eta *_{h 2^{n-k}}^{\prime} f_{k}\right)^{\wedge}=\widehat{f}_{k}$ which proves (1). Since $\operatorname{supp}\left(f_{k}\left(h 2^{n-k} .\right)\right)^{\wedge} \subseteq h 2^{n-k} 2^{k-1} \varepsilon Q \subset 2 \pi Q$, it follows by Lemma 4.1 (with $\rho=1$ ) that $\Gamma$

$$
\begin{aligned}
& \left\|f_{k}\right\|_{\ell_{p}\left(h 2^{n-k} \mathbb{Z}^{d}\right)} \\
& \quad=\left\|f_{k}\left(h 2^{n-k} \cdot\right)\right\|_{\ell_{p}\left(\mathbb{Z}^{d}\right)} \leq \operatorname{const}(d)\left\|f_{k}\left(h 2^{n-k} \cdot\right)\right\|_{L_{p}}=\operatorname{const}(d)\left(h 2^{n-k}\right)^{-d / p}\left\|f_{k}\right\|_{L_{p}}
\end{aligned}
$$

which proves (2). Noting that $f=\sum_{k=0}^{\infty} f_{k} \Gamma$ we obtain

$$
\left\|f-\sum_{k=0}^{n} f_{k}\right\|_{L_{p}} \leq \sum_{k=n+1}^{\infty}\left\|f_{k}\right\|_{L_{p}} \leq 2^{-(n+1) \gamma} \sum_{k=n+1}^{\infty} 2^{k \gamma}\left\|f_{k}\right\|_{L_{p}} \leq h^{\gamma}\|f\|_{B_{p}^{\gamma, 1}}
$$

which proves (3) and completes the proof of the claim.
It is convenient to define the scaling operator $\boldsymbol{\sigma}_{h}$ for $h>0$ as follows:

$$
\begin{aligned}
& \boldsymbol{\sigma}_{h} f:=f(\cdot / h), \quad \text { if } f: \mathbb{R}^{d} \rightarrow \mathbb{C} ; \\
& \boldsymbol{\sigma}_{h} \boldsymbol{f}:=\left(\boldsymbol{\sigma}_{h}\left(\boldsymbol{f}_{j}\right)\right)_{j \in \mathbb{Z}^{d}}, \quad \text { if } \boldsymbol{f} \in \mathcal{N} .
\end{aligned}
$$

$$
\begin{equation*}
\left\|\boldsymbol{\sigma}_{2^{k-n}} \boldsymbol{g}^{k}-\boldsymbol{\eta}\right\|_{\mathcal{N}} \leq A 2^{\gamma(k-n)}, \quad 0 \leq k \leq n . \tag{5.6}
\end{equation*}
$$

(Note: $2^{(k-n)}$ is playing the role of $h$ in (5.4) $\Gamma$ while $h$ is playing the role of $r$ in (5.4). Inequality (5.6) is a valid application of (5.4) because $0<h \leq 2^{(k-n)} \leq 1$.) Note that for $0 \leq k \leq n \Gamma \boldsymbol{\sigma}_{h} \boldsymbol{g}^{k} \in\left(S_{h}^{h}\right)^{\mathbb{Z}^{d}} \cap \mathcal{N}$ and it follows from Lemma 5.2 and from the assumption that $S_{h}^{h}$ is a closed subspace of $C\left(\mathbb{R}^{d}\right)$ that $\left(\boldsymbol{\sigma}_{h} \boldsymbol{g}^{k}\right) \cdot c \in S_{h}^{h}$ for all $c \in \ell_{\infty}$. Therefore $\Gamma$ by Claim 5.5 (2) $\Gamma$

$$
s_{h}:=\sum_{k=0}^{n}\left(\boldsymbol{\sigma}_{h} \boldsymbol{g}^{k}\right) \cdot\left(\boldsymbol{\sigma}_{h^{-1} 2^{k-n}} f_{k}\right) \in S_{h}^{h} .
$$

$$
\begin{aligned}
& \left\|s_{h}-\sum_{k=0}^{n} f_{k}\right\|_{L_{p}} \\
& =\left\|\sum_{k=0}^{n}\left(\boldsymbol{\sigma}_{h} \boldsymbol{g}^{k}-\boldsymbol{\sigma}_{h 2^{n-k}} \boldsymbol{\eta}\right) \cdot\left(\boldsymbol{\sigma}_{h^{-1} 2^{k-n}} f_{k}\right)\right\|_{L_{p}}, \quad \text { by Claim 5.5 (1) } \\
& \leq \sum_{k=0}^{n}\left(h 2^{n-k}\right)^{d / p}\left\|\left(\boldsymbol{\sigma}_{2^{k-n}} \boldsymbol{g}^{k}-\boldsymbol{\eta}\right) \cdot\left(\boldsymbol{\sigma}_{h^{-1} 2^{k-n}} f_{k}\right)\right\|_{L_{p}} \\
& \leq \sum_{k=0}^{n}\left(h 2^{n-k}\right)^{d / p}\left\|\boldsymbol{\sigma}_{2^{k-n}} \boldsymbol{g}^{k}-\boldsymbol{\eta}\right\|_{\mathcal{N}}\left\|f_{k}\right\|_{\ell_{p}\left(h 2^{n-k} \mathbb{Z}^{d}\right)}, \quad \text { by Lemma } 5.2 \Gamma \\
& \leq \sum_{k=0}^{n} A 2^{\gamma(k-n)} \operatorname{const}(d)\left\|f_{k}\right\|_{L_{p}}, \quad \text { by }(5.6) \text { and Claim } 5.5(2) \Gamma \\
& =\operatorname{const}(d) A 2^{-n \gamma} \sum_{k=0}^{n} 2^{k \gamma}\left\|f_{k}\right\|_{L_{p}} \leq \operatorname{const}(d, \gamma) A\|f\|_{B_{p}^{\gamma, 1}} h^{\gamma} .
\end{aligned}
$$

Thus $\Gamma$ with Claim 5.5 (3) in view $\Gamma$ the theorem is proved.
Returning to our original concern of approximation from $S^{h}\left(\phi_{h} ; \Xi\right)$ we have the following which is an immediate consequence of Theorem 5.3 (with $S_{r}:=S\left(\phi_{r} ; \Xi\right)$ ).

Corollary 5.7. Let $\left(\phi_{h}\right)_{h \in(0 . . ~}^{\left.h_{0}\right]}$ be a family of functions in $C\left(\mathbb{R}^{d}\right)$. Let $\eta \in \widehat{\mathcal{D}}$ and $\varepsilon \in(0 \ldots 2 \pi)$ be such that $\operatorname{supp} \hat{\eta} \subset \varepsilon Q$ and $\widehat{\eta}=1$ on $\frac{1}{2} \varepsilon Q$. Put $\boldsymbol{\eta}_{j}:=\eta(\cdot-j), j \in \mathbb{Z}^{d}$. Let $\Xi \subset \mathbb{R}^{d}$. If there exists $\gamma>0$ such that

$$
\sup _{0<r \leq h} \operatorname{dist}\left(\boldsymbol{\eta},\left(S^{h}\left(\phi_{r} ; \Xi\right)\right)^{\mathbb{Z}^{d}} \cap \mathcal{N} ; \mathcal{N}\right)=O\left(h^{\gamma}\right), \quad \text { as } h \rightarrow 0
$$

then $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma$ (in the sense of Definition 2.2) for all $1 \leq p \leq \infty$.

We now state the main result of this section. As mentioned before $\Gamma$ the set $\left(0 \ldots \gamma_{0}\right] \cup\left\{\gamma_{0}\right\}$ equals $\left(0 \ldots \gamma_{0}\right]$ when $\gamma_{0}>0$ and equals $\{0\}$ when $\gamma_{0}=0$.
Theorem 5.8. Let $\left(\phi_{h}\right)_{h \in\left(0 . . h_{0}\right]}$ be a family of functions in $C\left(\mathbb{R}^{d}\right)$ with at most polynomial growth at $\infty$, and assume that there exists $\gamma_{0} \geq 0$ such that for each $h \in\left(0 \ldots h_{0}\right]$, there exists a locally integrable function $\lambda_{h}$ such that $\widehat{\phi}_{h}$ can be identified on $\mathbb{R}^{d} \backslash 0$ with $|\cdot|^{-\gamma_{0}} \lambda_{h}$. Assume that there exists $\varepsilon \in(0 . .2 \pi)$ such that $\lambda_{h} \in C(\varepsilon Q)$ and $\left|\lambda_{h}\right|>0$ on $\varepsilon Q, \forall h \in$ $\left(0 . . h_{0}\right]$. Let $\eta \in \widehat{\mathcal{D}}$ be such that $\operatorname{supp} \widehat{\eta} \subset \varepsilon Q$ and $\widehat{\eta}=1$ on $\frac{1}{2} \varepsilon Q$. Assume that there exists $\mu \in\left(0 . . \gamma_{0}\right] \cup\left\{\gamma_{0}\right\}$ such that for all $0<r \leq h \leq 1$,

$$
\begin{align*}
& \left|\phi_{h}(x)\right|=o\left(|x|^{\gamma_{0}-\mu}\right) \quad a s|x| \rightarrow \infty  \tag{i}\\
& (1+|\cdot|)^{\gamma_{0}-\mu}\left(\frac{\widehat{\eta}(\cdot / h)|\cdot|^{\gamma_{0}}}{\lambda_{r}}\right)^{\vee} \in L_{1} . \tag{ii}
\end{align*}
$$

Let $\sigma \in \mathcal{D}$ satisfy $\operatorname{supp} \sigma \subset 2 \pi Q$ and $\sigma=1$ on $\varepsilon Q$. If there exists $\gamma \in(0 \ldots \infty)$ such that

$$
\sup _{0<r \leq h}\left\|\left(\frac{\widehat{\eta}(\cdot / h)|\cdot|^{\gamma_{0}}}{\lambda_{r}}\right)^{\vee}\right\|_{L_{1}} \sum_{j \in \mathbb{Z}^{d}}\left\|\left((1-\sigma)|\cdot|^{-\gamma_{0}} \lambda_{r}\right)^{\vee}\right\|_{L_{\infty}(j+Q)}=O\left(h^{\gamma}\right), \quad \text { as } h \rightarrow 0 \text {, }
$$

then $\left(S^{h}\left(\phi_{h} ; \Xi\right)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma$ (in the sense of Definition 2.2) for all $1 \leq p \leq \infty$ whenever $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d}$.

Conditions (i) $\Gamma$ (ii) serve to ensure that a certain approximant actually belongs to $S^{h}\left(\phi_{h} ; \Xi\right)$. As far as the approximation order is concerned $\Gamma$ the item of significance is the behavior of $\Gamma(r, h)$ as $r \leq h \rightarrow 0 \Gamma$ where

$$
\Gamma(r, h):=\left\|\left(\frac{\widehat{\eta}(\cdot / h)|\cdot|^{\gamma_{0}}}{\lambda_{r}}\right)^{\vee}\right\|_{L_{1}} \sum_{j \in \mathbb{Z}^{d}}\left\|\left((1-\sigma)|\cdot|^{-\gamma_{0}} \lambda_{r}\right)^{\vee}\right\|_{L_{\infty}(j+Q)} .
$$

Note that there are two factors in the definition of $\Gamma(r, h)$. In the stationary case $\Gamma$ the second factor is fixed (independent of $r$ and $h$ ) and so it is useful only when it is 0 ; the significance of the first factor $\Gamma$

$$
\left\|\left(\frac{\widehat{\eta}(\cdot / h)|\cdot|^{\gamma_{0}}}{\lambda}\right)^{\vee}\right\|_{L_{1}}=h^{\gamma_{0}}\left\|\left(\frac{\widehat{\eta}|\cdot|^{\gamma_{0}}}{\lambda(h \cdot)}\right)^{\vee}\right\|_{L_{1}}
$$

is that it is $O\left(h^{\gamma_{0}}\right)$ if $\left(\frac{\widehat{\eta}}{\lambda(h \cdot)}\right)^{\vee} \in L_{1}$ for sufficiently small $h>0$. In the non-stationary case $\Gamma$ the second factor is usually most responsible for the decay of $\Gamma(r, h)$.

In view of Corollary 5.7 Tin order to prove Theorem 5.8 Гit suffices to prove the following:
Lemma 5.9. Under the hypothesis of Theorem 5.8, there exists $\delta_{0}>0$ such that if $\boldsymbol{\delta}(\Xi) \leq$ $\delta_{0}$, then

$$
\begin{aligned}
& \operatorname{dist}\left(\boldsymbol{\eta},\left(S^{h}\left(\phi_{r} ; \Xi\right)\right)^{\mathbb{Z}^{d}} \cap \mathcal{N} ; \mathcal{N}\right) \\
& \quad \leq \operatorname{const}\left(d, \delta_{0}\right)\left\|\left(\frac{\hat{\eta}(\cdot / h)|\cdot|^{\gamma_{0}}}{\lambda_{r}}\right)^{\vee}\right\|_{L_{1}} \sum_{j \in \mathbb{Z}^{d}}\left\|\left((1-\sigma)|\cdot|^{-\gamma_{0}} \lambda_{r}\right)^{\vee}\right\|_{L_{\infty}(j+Q)},
\end{aligned}
$$

for all $0<r \leq h \leq h_{0}$.
Proof. Put $\tau_{r, h}:=\left(\frac{\widehat{\eta} \cdot / \cdot / h)|\cdot|^{\gamma_{0}}}{\lambda_{r}}\right)^{\vee}$ and $\psi_{r}:=\left(\left.(1-\sigma)\right|^{-\gamma_{0}} \lambda_{r}\right)^{\vee}$. Without loss of generality we may assume that $\sum_{j \in \mathbb{Z}^{d}}\left\|\psi_{r}\right\|_{L_{\infty}(j+Q)}<\infty$ and $h_{0}=1$. Define $\rho:=(1+|\cdot|)^{\gamma_{0}-\mu} \Gamma$ and note that $1 \leq \rho(j+k) \leq \rho(j) \rho(k)$ for all $j, k \in \mathbb{Z}^{d}$. There exists $\varepsilon_{1} \in(0 \ldots \pi)$ such that $\operatorname{supp} \sigma \subset\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d}$. Let $\zeta \in \widehat{\mathcal{D}}$ satisfy $\operatorname{supp} \widehat{\zeta} \subset\left[-\pi-\varepsilon_{1} \ldots \pi+\varepsilon_{1}\right]^{d} \Gamma \widehat{\zeta}=1$ on $\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d} \Gamma$ and $\sum_{j \in \mathbb{Z}^{d}} \widehat{\zeta}(\cdot+2 \pi j)=1$. Let $\delta(\zeta, \rho)$ be as in Lemma $4.3 \Gamma$ and let $\delta_{0} \in(0 \ldots \delta(\zeta, \rho))$. Fix $0<r \leq h \leq 1 \Gamma$ and let $\Xi$ be any perturbation of $\mathbb{Z}^{d}$ satisfying $\boldsymbol{\delta}(\Xi) \leq \delta_{0}$. Using the countable axiom of choice ${ }^{1} \Gamma$ there exists a sequence $\left(\xi_{j}\right)_{j \in \mathbb{Z}^{d}}$ with the

[^0]property that $\xi_{j} \in\left(j+\delta_{0} \bar{Q}\right) \cap \Xi$ for all $j \in \mathbb{Z}^{d}$. Let $\Lambda$ be as in Lemma 4.3Гand define
\[

$$
\begin{aligned}
& a_{k}(j):=h^{-d} \tau_{r, h}(j-k / h), \quad j, k \in \mathbb{Z}^{d} ; \\
& b_{k}:=\Lambda a_{k}, \quad k \in \mathbb{Z}^{d} .
\end{aligned}
$$
\]

Note that by (ii) of Theorem 5.8 and Lemma 4.1 $\Gamma$ it follows that $\rho a_{k} \in \ell_{1}$ and hence $b_{k}$ is well defined. By Lemma 4.3 (3) $\Gamma$

$$
\begin{equation*}
\left\|\rho b_{k}\right\|_{\ell_{1}} \leq \operatorname{const}\left(d, \zeta, \rho, \delta_{0}\right)\left\|\rho a_{k}\right\|_{\ell_{1}}, \quad \forall k \in \mathbb{Z}^{d} \tag{5.10}
\end{equation*}
$$

Hence by (i) of Theorem $5.8 \Gamma$

$$
g_{k}:=\sum_{j \in \mathbb{Z}^{d}} b_{k}(j) \phi_{r}\left(\cdot / h-\xi_{j}\right) \in S^{h}\left(\phi_{r} ; \Xi\right), \quad \forall k \in \mathbb{Z}^{d}
$$

Claim 5.11.

$$
g_{k}=\sum_{j \in \mathbb{Z}^{d}} b_{k}(j) \psi_{r}\left(\cdot / h-\xi_{j}\right)+\eta(\cdot-k), \quad \forall k \in \mathbb{Z}^{d}
$$

proof. Fix $k \in \mathbb{Z}^{d}$ and put $g:=\sum_{j \in \mathbb{Z}^{d}} b_{k}(j) \psi_{r}\left(\cdot-\xi_{j}\right)+\eta(h \cdot-k)$. Since $g \in L_{1}\left(\right.$ as $b_{k} \in \ell_{1}$ and $\psi_{r} \in L_{1}$ ) and with Lemma 4.8 in view $\Gamma$ in order to prove the claimГit suffices to show that

$$
\begin{equation*}
\widehat{g}(x)=|x|^{-\gamma_{0}} \lambda_{r}(x) \sum_{j \in \mathbb{Z}^{d}} b_{k}(j) e_{-\xi_{j}}(x), \quad \forall x \in \mathbb{R}^{d} \backslash 0 \tag{5.12}
\end{equation*}
$$

First note that

$$
\widehat{g}=h^{-d} e_{-k / h} \widehat{\eta}(\cdot / h)+\widehat{\psi}_{r} \sum_{j \in \mathbb{Z}^{d}} b_{k}(j) e_{-\xi_{j}}=h^{-d} e_{-k / h} \widehat{\eta}(\cdot / h)+(1-\sigma)|\cdot|^{-\gamma_{0}} \lambda_{r} \sum_{j \in \mathbb{Z}^{d}} b_{k}(j) e_{-\xi_{j}} .
$$

Since $\sigma=1$ on $\operatorname{supp} \hat{\eta}$ and $\sigma=0$ outside of $\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d} \Gamma$ in order to establish (5.12) $\Gamma$ and hence prove the claim $\Gamma$ it suffices to show that

$$
\sum_{j \in \mathbb{Z}^{d}} b_{k}(j) e_{-\xi_{j}}(x)=h^{-d} e_{-k / h}(x) \frac{\widehat{\eta}(x / h)|x|^{\gamma_{0}}}{\lambda_{r}(x)}, \quad \forall x \in\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d} .
$$

For that let $x \in\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d}$. Note that on the one hand $\Gamma$

$$
\begin{aligned}
& \left(\zeta *^{\prime}\left(h^{-d} \tau_{r, h}(\cdot-k / h)\right)\right) \uparrow(x) \\
& =h^{-d} \widehat{\zeta}(x) \sum_{j \in \mathbb{Z}^{d}}\left(\tau_{r, h}(\cdot-k / h)\right) \uparrow(x-2 \pi j), \quad \text { by Lemma } 4.2 \Gamma \\
& =h^{-d} \sum_{j \in \mathbb{Z}^{d}} e_{-k / h}(x+2 \pi j) \widehat{\tau}_{r, h}(x+2 \pi j), \quad \text { since } \widehat{\zeta}=1 \text { on }\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d}, \\
& =h^{-d} e_{-k / h}(x) \frac{\widehat{\eta}(x / h)|x|^{\gamma_{0}}}{\lambda_{r}(x)}, \quad \text { since supp } \widehat{\tau}_{r, h} \subset\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d} .
\end{aligned}
$$

While on the other hand $\Gamma$

$$
\begin{aligned}
& \left(\zeta *^{\prime}\left(h^{-d} \tau_{r, h}(\cdot-k / h)\right)\right) \uparrow(x)=\left(\sum_{j \in \mathbb{Z}^{d}} a_{k}(j) \zeta(\cdot-j)\right) \widehat{ }(x) \\
& =\widehat{\zeta}(x) \sum_{j \in \mathbb{Z}^{d}} a_{k}(j) e_{-j}(x)=\sum_{j \in \mathbb{Z}^{d}} a_{k}(j) e_{-j}(x)=\sum_{j \in \mathbb{Z}^{d}} b_{k}(j) e_{-\xi_{j}}(x),
\end{aligned}
$$

by Remark 4.4 (as $x \in\left[-\pi+\varepsilon_{1} \ldots \pi-\varepsilon_{1}\right]^{d}$ ). Hence the claim.
Define $\boldsymbol{g}:=\left(g_{k}\right)_{k \in \mathbb{Z}^{d}} \in S^{h}\left(\phi_{r} ; \Xi\right)^{\mathbb{Z}^{d}}$. Then by Claim $5.11 \Gamma$

$$
\begin{equation*}
(\boldsymbol{g}-\boldsymbol{\eta})_{k}=\sum_{j \in \mathbb{Z}^{d}} b_{k}(j) \psi_{r}\left(\cdot / h-\xi_{j}\right), \quad \forall k \in \mathbb{Z}^{d} \tag{5.13}
\end{equation*}
$$

Recall that in order to show that $\boldsymbol{g}-\boldsymbol{\eta} \in \mathcal{N} \Gamma$ we must show that $\|\boldsymbol{g}-\boldsymbol{\eta}\|_{\mathcal{N}}<\infty$ and additionally that for all compact $K \subset \mathbb{R}^{d} \Gamma \sum_{k \in \mathbb{Z}^{d}}\left\|(\boldsymbol{g}-\boldsymbol{\eta})_{k}\right\|_{L_{\infty}(K)}<\infty$. For the latter $\Gamma$ let $K \subset \mathbb{R}^{d}$ be compact. Then

$$
\begin{align*}
& \sum_{k \in \mathbb{Z}^{d}}\left\|(\boldsymbol{g}-\boldsymbol{\eta})_{k}\right\|_{L_{\infty}(K)} \\
& \leq \sum_{k \in \mathbb{Z}^{d}} \sum_{j \in \mathbb{Z}^{d}}\left|b_{k}(j)\right|\left\|\psi_{r}\left(\cdot / h-\xi_{j}\right)\right\|_{L_{\infty}(K)}, \quad \text { by }(5.13), \\
& =\sum_{j \in \mathbb{Z}^{d}}\left\|\psi_{r}\left(\cdot / h-\xi_{j}\right)\right\|_{L_{\infty}(K)} \sum_{k \in \mathbb{Z}^{d}}\left|b_{k}(j)\right|, \quad \text { by Fubini's Theorem, }  \tag{5.14}\\
& \leq \operatorname{const}(K, h)\left(\sum_{j \in \mathbb{Z}^{d}}\left\|\psi_{r}\right\|_{L_{\infty}(j+Q)}\right) \sup _{j \in \mathbb{Z}^{d}} \sum_{k \in \mathbb{Z}^{d}}\left|b_{k}(j)\right|
\end{align*}
$$

Now $\Gamma$ if $j \in \mathbb{Z}^{d}$ and $n \in \mathbb{N} \Gamma$ then

$$
\begin{aligned}
& \sum_{|k| \leq n}\left|b_{k}(j)\right| \leq\left\|\sum_{|k| \leq n} \operatorname{signum}\left(\overline{b_{k}(j)}\right) b_{k}\right\|_{\ell_{\infty}}=\left\|\Lambda\left(\sum_{|k| \leq n} \operatorname{signum}\left(\overline{b_{k}(j)}\right) a_{k}\right)\right\|_{\ell_{\infty}} \\
& \leq \operatorname{const}\left(d, \zeta, \delta_{0}\right)\left\|\sum_{|k| \leq n} \operatorname{signum}\left(\overline{b_{k}(j)}\right) a_{k}\right\|_{\ell_{\infty}}, \quad \text { by Lemma } 4.3(3) \Gamma \\
& \leq \operatorname{const}\left(d, \zeta, \delta_{0}\right) \sup _{\ell \in \mathbb{Z}^{d}} \sum_{k \in \mathbb{Z}^{d}}\left|a_{k}(\ell)\right| .
\end{aligned}
$$

Hence $\Gamma$

$$
\begin{align*}
& \sup _{j \in \mathbb{Z}^{d}} \sum_{k \in \mathbb{Z}^{d}}\left|b_{k}(j)\right| \leq \operatorname{const}\left(d, \zeta, \delta_{0}\right) \sup _{j \in \mathbb{Z}^{d}} \sum_{k \in \mathbb{Z}^{d}}\left|a_{k}(j)\right| \\
& =\operatorname{const}\left(d, \zeta, \delta_{0}\right) \sup _{j \in \mathbb{Z}^{d}} h^{-d}\left\|\tau_{r, h}(\cdot / h+j)\right\|_{\ell_{1}}  \tag{5.15}\\
& \leq \operatorname{const}\left(d, \zeta, \delta_{0}\right) h^{-d}\left\|\tau_{r, h}(\cdot / h)\right\|_{L_{1}}, \quad \text { by Lemma } 4.1 \Gamma \\
& =\operatorname{const}\left(d, \zeta, \delta_{0}\right)\left\|\tau_{r, h}\right\|_{L_{1}} .
\end{align*}
$$

Combining (5.15) and (5.14) yields $\sum_{k \in \mathbb{Z}^{d}}\left\|(\boldsymbol{g}-\boldsymbol{\eta})_{k}\right\|_{L_{\infty}(K)}<\infty$. Next we estimate $\|\boldsymbol{g}-\boldsymbol{\eta}\|_{\mathcal{N}}$. If $k \in \mathbb{Z}^{d} \Gamma$ then

$$
\begin{aligned}
& \left\|(\boldsymbol{g}-\boldsymbol{\eta})_{k}\right\|_{L_{1}} \leq \sum_{j \in \mathbb{Z}^{d}}\left|b_{k}(j)\right|\left\|\psi_{r}\left(\cdot / h-\xi_{j}\right)\right\|_{L_{1}}=h^{d}\left\|\psi_{r}\right\|_{L_{1}}\left\|b_{k}\right\|_{\ell_{1}} \\
& \leq h^{d}\left\|\psi_{r}\right\|_{L_{1}} \operatorname{const}\left(d, \zeta, \delta_{0}\right)\left\|a_{k}\right\|_{\ell_{1}}, \quad \text { by Lemma } 4.3(1) \Gamma \\
& =\operatorname{const}\left(d, \zeta, \delta_{0}\right)\left\|\psi_{r}\right\|_{L_{1}}\left\|\tau_{r, h}(\cdot-k / h)\right\|_{\ell_{1}} \\
& \leq \operatorname{const}\left(d, \zeta, \delta_{0}\right)\left\|\psi_{r}\right\|_{L_{1}}\left\|\tau_{r, h}\right\|_{L_{1}}, \quad \text { by Lemma } 4.1 \Gamma \\
& \leq \operatorname{const}\left(d, \zeta, \delta_{0}\right)\left\|\tau_{r, h}\right\|_{L_{1}} \sum_{j \in \mathbb{Z}^{d}}\left\|\psi_{r}\right\|_{L_{\infty}(j+Q)}
\end{aligned}
$$

Hence $\Gamma \sup _{k \in \mathbb{Z}^{d}}\left\|(\boldsymbol{g}-\boldsymbol{\eta})_{k}\right\|_{L_{1}} \leq \operatorname{const}\left(d, \zeta, \delta_{0}\right)\left\|\tau_{r, h}\right\|_{L_{1}} \sum_{j \in \mathbb{Z}^{d}}\left\|\psi_{r}\right\|_{L_{\infty}(j+Q)}$. On the other hand $\Gamma$

$$
\left\|\sum_{k \in \mathbb{Z}^{d}}\left|(\boldsymbol{g}-\boldsymbol{\eta})_{k}\right|\right\|_{L_{\infty}} \leq \sup _{x \in \mathbb{R}^{d}} \sum_{k \in \mathbb{Z}^{d}} \sum_{j \in \mathbb{Z}^{d}}\left|b_{k}(j)\right|\left|\psi_{r}\left(x / h-\xi_{j}\right)\right|
$$

$$
=\sup _{x \in \mathbb{R}^{d}} \sum_{j \in \mathbb{Z}^{d}}\left|\psi_{r}\left(x / h-\xi_{j}\right)\right| \sum_{k \in \mathbb{Z}^{d}}\left|b_{k}(j)\right|, \quad \text { by Fubini's theorem } \Gamma
$$

$$
\leq\left\|\sum_{j \in \mathbb{Z}^{d}}\left|\psi_{r}\left(\cdot-\xi_{j}\right)\right|\right\|_{L_{\infty}} \sup _{j \in \mathbb{Z}^{d}} \sum_{k \in \mathbb{Z}^{d}}\left|b_{k}(j)\right|
$$

$$
\leq \operatorname{const}\left(d, \zeta, \delta_{0}\right) \sum_{j \in \mathbb{Z}^{d}}\left\|\psi_{r}\right\|_{L_{\infty}(j+Q)}\left\|\tau_{r, h}\right\|_{L_{1}}, \quad \text { by (5.15). }
$$

Therefore $\Gamma\|\boldsymbol{g}-\boldsymbol{\eta}\|_{\mathcal{N}} \leq \operatorname{const}\left(d, \zeta, \delta_{0}\right)\left\|\tau_{r, h}\right\|_{L_{1}} \sum_{j \in \mathbb{Z}^{d}}\left\|\psi_{\boldsymbol{r}}\right\|_{L_{\infty}(j+\boldsymbol{Q})}$. In particular「 $\boldsymbol{g}-\boldsymbol{\eta} \in \mathcal{N} \Gamma$ and since $\boldsymbol{\eta} \in \mathcal{N}$ Гit follows that $\boldsymbol{g} \in \mathcal{N}$; hence $\Gamma \boldsymbol{g} \in S^{h}\left(\phi_{r} ; \Xi\right)^{Z^{d}} \cap \mathcal{N} \Gamma$ and so we conclude that

$$
\operatorname{dist}\left(\boldsymbol{\eta},\left(S^{h}\left(\phi_{r} ; \Xi\right)\right)^{\mathbb{Z}^{d}} \cap \mathcal{N} ; \mathcal{N}\right) \leq \operatorname{const}\left(d, \zeta, \delta_{0}\right)\left\|\tau_{r, h}\right\|_{L_{1}} \sum_{j \in \mathbb{Z}^{d}}\left\|\psi_{r}\right\|_{L_{\infty}(j+Q)} .
$$

Taking the infimum over all appropriate $\zeta$ completes the proof.

## 6. Proof of Theorem 3.1

The following string of lemmata will be used to prove Theorem 3.1 at the end of this section.

Lemma 6.1. Let $0 \leq a<b \leq \infty$, and let $F \in C^{m}(a . . b)$ for some $m \in \mathbb{N}$. Then there exist $p_{\alpha, k} \in C^{\infty}\left(\mathbb{R}^{d} \backslash 0\right), 1 \leq k \leq|\alpha| \leq m$, such that $p_{\alpha, k}$ is homogeneous of degree $k-|\alpha|$ and

$$
\begin{equation*}
D^{\alpha}(F(|\cdot|))=\sum_{k=1}^{|\alpha|} p_{\alpha, k} F^{(k)}(|\cdot|) \tag{6.2}
\end{equation*}
$$

on $\Omega:=\left\{x \in \mathbb{R}^{d}: a<|x|<b\right\}$ for all $1 \leq|\alpha| \leq m$.
Proof. If $|\alpha|=1 \Gamma$ then $D^{\alpha}(F(|\cdot|))=F^{\prime}(|\cdot|) D^{\alpha}|\cdot|$ which settles the case $m=1$ since $p_{\alpha, 1}:=D^{\alpha}|\cdot| \in C^{\infty}\left(\mathbb{R}^{d} \backslash 0\right)$ and is homogeneous of degree 0 . Proceeding by induction on $m \Gamma$ assume that (6.2) holds for all $1 \leq|\alpha| \leq m-1$ and consider $m$. Let $|\alpha|=m-1$ and $|\beta|=1$. Then

$$
\begin{aligned}
& D^{\alpha+\beta}(F(|\cdot|))=D^{\beta}\left(\sum_{k=1}^{|\alpha|} p_{\alpha, k} F^{(k)}(|\cdot|)\right), \quad \text { by the induction hypothesis } \Gamma \\
& =\sum_{k=1}^{|\alpha|}\left(\left(D^{\beta} p_{\alpha, k}\right) F^{(k)}(|\cdot|)+p_{\alpha, k} F^{(k+1)}(|\cdot|) D^{\beta}|\cdot|\right), \quad \text { since }|\beta|=1, \\
& =\sum_{k=1}^{|\alpha|}\left(D^{\beta} p_{\alpha, k}\right) F^{(k)}(|\cdot|)+\sum_{k=2}^{|\alpha|+1} p_{\alpha, k-1}\left(D^{\beta}|\cdot|\right) F^{(k)}(|\cdot|) .
\end{aligned}
$$

Noting that both $D^{\beta} p_{\alpha, k}$ and $p_{\alpha, k-1}\left(D^{\beta}|\cdot|\right)$ are in $C^{\infty}\left(\mathbb{R}^{d} \backslash 0\right)$ and homogeneous of degree $k-|\alpha+\beta|$ Twe complete the induction.

Lemma 6.3. Let $n \geq d, \varepsilon \in(0 . .1)$, and $\delta \in(0 \ldots \infty)$. Let
$F \in C[0 \ldots \delta) \cap C^{n}(0 \ldots \delta)$. If $\nu \in \mathcal{D}(\delta B)$, then

$$
\begin{aligned}
& \left\|(1+|\cdot|)^{n-d+\varepsilon / 2}(\nu F(|\cdot|))^{\vee}\right\|_{L_{1}} \\
& \quad \leq \operatorname{const}(d, n, \delta, \varepsilon, \nu)\left(\sup _{0<\rho<\delta}|F(\rho)|+\max _{1 \leq k \leq n} \sup _{0<\rho<\delta} \frac{\left|F^{(k)}(\rho)\right|}{\rho^{n-d+\varepsilon-k}}\right) .
\end{aligned}
$$

Proof. Without loss of generality assume that the right side of our inequality is finite. Let $\nu \in \mathcal{D}(\delta B) \Gamma$ and let $q \in(1 . .2]$ be the middling value satisfying $\varepsilon>d-d / q>\varepsilon / 2$. Put $\tau:=(\nu F(|\cdot|))^{\vee} \Gamma$ and let $p$ be the exponent conjugate to $q$. Then

$$
\begin{aligned}
& \left\|(1+|\cdot|)^{n-d+\varepsilon / 2} \tau\right\|_{L_{1}} \leq \operatorname{const}(d, n, \varepsilon) \sum_{j \in \mathbb{Z}^{d}}(1+|j|)^{-d+\varepsilon / 2}\left\|(1+|\cdot|)^{n} \tau\right\|_{L_{1}(j+Q)} \\
& \leq \operatorname{const}(d, n, \varepsilon) \sum_{j \in \mathbb{Z}^{d}}(1+|j|)^{-d+\varepsilon / 2}\left\|(1+|\cdot|)^{n} \tau\right\|_{L_{p}(j+Q)} \\
& \leq \operatorname{const}(d, n, \varepsilon)\left(\sum_{j \in \mathbb{Z}^{d}}(1+|j|)^{(-d+\varepsilon / 2) q}\right)^{1 / q}\left\|(1+|\cdot|)^{n} \tau\right\|_{L_{p}}, \quad \text { by Hölder's inequality. }
\end{aligned}
$$

Note that $q(-d+\varepsilon / 2)<-d$ follows from the assumption $d-d / q>\varepsilon / 2$. Therefore $\Gamma$

$$
\begin{equation*}
\left\|(1+|\cdot|)^{n-d+\varepsilon / 2} \tau\right\|_{L_{1}} \leq \operatorname{const}(d, n, \varepsilon)\left\|(1+|\cdot|)^{n} \tau\right\|_{L_{p}} \leq \operatorname{const}(d, n, \varepsilon)\|\widehat{\tau}\|_{W_{q}^{n}\left(\mathbb{R}^{d}\right)}, \tag{6.4}
\end{equation*}
$$

by the (extended) Hausdorff-Young Theorem. Put $\Omega:=\operatorname{supp} \nu$. Then

$$
\begin{aligned}
& \|\widehat{\tau}\|_{W_{q}^{n}\left(\mathbb{R}^{d} \backslash 0\right)} \leq \operatorname{const}(d, n, \varepsilon, \nu)\|F(|\cdot|)\|_{W_{q}^{n}(\Omega \backslash 0)} \leq \operatorname{const}(d, n, \varepsilon, \nu) \max _{|\alpha| \leq n}\left\|D^{\alpha}(F(|\cdot|))\right\|_{L_{q}(\Omega \backslash 0)} \\
& \leq \operatorname{const}(d, n, \varepsilon, \nu)\left(\|F(|\cdot|)\|_{L_{q}(\Omega \backslash 0)}+\max _{1 \leq|\alpha| \leq n} \sum_{k=1}^{|\alpha|}\left\||\cdot|^{k-|\alpha|} F^{(k)}(|\cdot|)\right\|_{L_{q}(\Omega \backslash 0)}\right), \text { by L. } 6.1 \Gamma \\
& \leq \operatorname{const}(d, n, \varepsilon, \nu)\left(\sup _{0<\rho<\delta}|F(\rho)|+\max _{1 \leq k \leq n}\left\||\cdot|^{k-n} F^{(k)}(|\cdot|)\right\|_{L_{q}(\Omega \backslash 0)}\right) \\
& \leq \operatorname{const}(d, n, \varepsilon, \nu)\left(\sup _{0<\rho<\delta}|F(\rho)|+\left\||\cdot|^{\varepsilon-d}\right\|_{L_{q}(\Omega \backslash 0)} \max _{1 \leq k \leq n}\left\|\left.|\cdot|\right|^{k-n+d-\varepsilon} F^{(k)}(|\cdot|)\right\|_{L_{\infty}(\delta B \backslash 0)}\right) \\
& \leq \operatorname{const}(d, n, \delta, \varepsilon, \nu)\left(\sup _{0<\rho<\delta}|F(\rho)|+\max _{1 \leq k \leq n} \sup _{0<\rho<\delta} \frac{\left|F^{(k)}(\rho)\right|}{\rho^{n-d+\varepsilon-k}}\right)
\end{aligned}
$$

as $q(\varepsilon-d)>-d$ is implied by $\varepsilon>d-d / q$. So with (6.4) in view $\Gamma$ in order to complete the proof of the lemma厂we need only show that $D^{\alpha} \widehat{\tau} \in L_{q}$ for all $|\alpha| \leq n$. Since $D^{\alpha} \widehat{\tau} \in$ $L_{q}\left(\mathbb{R}^{d} \backslash 0\right)$ has been established $\Gamma$ it suffices to show that

$$
\begin{equation*}
\left\langle g, D^{\alpha} \widehat{\tau}\right\rangle=\int_{\mathbb{R}^{d} \backslash 0} g D^{\alpha} \widehat{\tau} d m \tag{6.5}
\end{equation*}
$$

for all $g \in \mathcal{D} \Gamma|\alpha| \leq n$. So let $g \in \mathcal{D} \Gamma|\alpha| \leq n$. Since $F \in C([0 \ldots \delta)) \Gamma(6.5)$ holds if $\alpha=0$; so assume $|\alpha|>0$. By Lemma 6.1 $\Gamma$

$$
\begin{aligned}
& \left|D^{\alpha}(F(|\cdot|))\right|=\left|\sum_{k=1}^{|\alpha|} p_{\alpha, k} F^{(k)}(|\cdot|)\right| \\
& \leq \operatorname{const}(d, n, \varepsilon, F) \sum_{k=1}^{|\alpha|}|\cdot|^{k-|\alpha|}|\cdot|^{\varepsilon+n-d-k} \leq \operatorname{const}(d, n, \varepsilon, F)|\cdot|^{\varepsilon+n-d-|\alpha|} .
\end{aligned}
$$

Thus $F(|\cdot|) \in C\left(\mathbb{R}^{d}\right) \cap C^{n-d}\left(\mathbb{R}^{d} \backslash 0\right)$ and the restriction of $D^{\alpha}(F(|\cdot|))$ to $\mathbb{R}^{d} \backslash 0$ admits a continuous extension to all of $\mathbb{R}^{d}$ for all $|\alpha| \leq n-d$. It follows that $F(|\cdot|) \in C^{n-d}\left(\mathbb{R}^{d}\right)$. Consequently $\Gamma \hat{\tau}=\nu F(|\cdot|) \in C^{n-d}\left(\mathbb{R}^{d}\right)$ and (6.5) holds whenever $|\alpha| \leq n-d$. So assume $n-d<|\alpha| \leq n$. Let $p \in \Pi_{n-d}$ be the Taylor approximation to $\hat{\tau}$ (at 0 ). Let $\sigma \in \mathcal{D}(B)$ be identically 1 on a neighborhood of $0 \Gamma$ and define $\sigma_{\ell}:=\sigma(\ell \cdot) \Gamma \ell \in \mathbb{N}$. Then

$$
\left\langle g, D^{\alpha} \widehat{\tau}\right\rangle=\left\langle\sigma_{\ell} g, D^{\alpha} \widehat{\tau}\right\rangle+\left\langle\left(1-\sigma_{\ell}\right) g, D^{\alpha} \widehat{\tau}\right\rangle
$$

Since $\left(1-\sigma_{\ell}\right) g \in \mathcal{D}\left(\mathbb{R}^{d} \backslash 0\right)$ and $\hat{\tau} \in C^{n}\left(\mathbb{R}^{d} \backslash 0\right) \Gamma$ we have

$$
\left\langle\left(1-\sigma_{\ell}\right) g, D^{\alpha} \widehat{\tau}\right\rangle=\int_{\mathbb{R}^{d} \backslash 0}\left(1-\sigma_{\ell}\right) g D^{\alpha} \widehat{\tau} d m \rightarrow \int_{\mathbb{R}^{d} \backslash 0} g D^{\alpha} \widehat{\tau} d m \quad \text { as } \ell \rightarrow \infty
$$

Thus $\Gamma$ in order to establish (6.5) it suffices to show that $\left\langle\sigma_{\ell} g, D^{\alpha} \hat{\tau}\right\rangle \rightarrow 0$ as $\ell \rightarrow \infty$. Since $|\alpha|>n-d \Gamma$ we have $D^{\alpha} p=0$. Hence

$$
\begin{aligned}
& \left|\left\langle\sigma_{\ell} g, D^{\alpha} \widehat{\tau}\right\rangle\right|=\left|\left\langle\sigma_{\ell g}, D^{\alpha}(\widehat{\tau}-p)\right\rangle\right|=\left|\left\langle D^{\alpha}\left(\sigma_{\ell g}\right), \widehat{\tau}-p\right\rangle\right| \\
& \leq\left\|D^{\alpha}\left(\sigma_{\ell g}\right)\right\|_{L_{\infty}}\|\widehat{\tau}-p\|_{L_{\infty}(B / \ell)} m(B / \ell)=O\left(\ell^{|\alpha|}\right) o\left(\ell^{-(n-d)}\right) O\left(\ell^{-d}\right)=o(1)
\end{aligned}
$$

as $\ell \rightarrow 0$.

Lemma 6.6. Let $\varepsilon \in(0 \ldots 1), \delta \in(0 \ldots \infty)$. Let $G \in C[0 \ldots \delta) \cap C^{d}(0 \ldots \delta)$ satisfy $G \neq 0$ on all of $[0 \ldots \delta)$. If $\nu \in \mathcal{D}(\delta B)$, then

$$
\left\|(1+|\cdot|)^{\varepsilon / 2}\left(\frac{\nu}{G(|\cdot|)}\right)^{\vee}\right\|_{L_{1}} \leq \operatorname{const}(d, \delta, \varepsilon, \nu)\left(1+\max _{1 \leq k \leq d} \sup _{0<\rho<\delta}\left|\frac{G^{(k)}(\rho)}{G(\rho) \rho^{\varepsilon-k}}\right|\right)^{d} \sup _{0<\rho<\delta} \frac{1}{|G(\rho)|}
$$

Proof. Put $F(\rho):=\frac{1}{G(\rho)} \Gamma 0 \leq \rho<\delta$. Then $F \in C[0 \ldots \delta) \cap C^{d}(0 \ldots \delta) \Gamma$ and so in view of Lemma 6.3 Гin order to prove our lemmaГit suffices to show that

$$
\max _{1 \leq k \leq d} \sup _{0<\rho<\delta} \frac{\left|F^{(k)}(\rho)\right|}{\rho^{\varepsilon-k}} \leq \operatorname{const}(d, \delta, \varepsilon, \nu)\left(1+\max _{1 \leq k \leq d} \sup _{0<\rho<\delta}\left|\frac{G^{(k)}(\rho)}{G(\rho) \rho^{\varepsilon-k}}\right|\right)^{d} \sup _{0<\rho<\delta} \frac{1}{|G(\rho)|}
$$

For this it suffices to prove that for all $1 \leq k \leq d \Gamma$

$$
\begin{equation*}
\left|G(\rho) F^{(k)}(\rho)\right| \leq \operatorname{const}(d, \delta, \varepsilon, \nu)\left(1+\max _{1 \leq j \leq k} \sup _{0<\rho<\delta}\left|\frac{G^{(j)}(\rho)}{G(\rho) \rho^{\varepsilon-j}}\right|\right)^{k} \rho^{\varepsilon-k}, \quad 0<\rho<\delta . \tag{6.7}
\end{equation*}
$$

Differentiating the identity $F(\rho) G(\rho)=1$ and solving for $G(\rho) F^{(k)}(\rho)$ yields

$$
\begin{equation*}
G(\rho) F^{(k)}(\rho)=-\sum_{j=0}^{k-1}\binom{k}{j} F^{(j)}(\rho) G^{(k-j)}(\rho), \quad 0<\rho<\delta, 1 \leq k \leq d \tag{6.8}
\end{equation*}
$$

For $k=1$ this reads $G(\rho) F^{\prime}(\rho)=-\frac{G^{\prime}(\rho)}{G(\rho)}=-\frac{G^{\prime}(\rho)}{G(\rho) \rho^{\varepsilon-1}} \rho^{\varepsilon-1}$ which proves (6.7) for the case $k=1$. Proceeding by inductionГassume that (6.7) holds for all $k \Gamma 1 \leq k \leq k^{\prime}<d \Gamma$ and consider $k=k^{\prime}+1$. Let $\rho \in(0, \delta)$. In view of $(6.8) \Gamma$ in order to prove ( 6.7$) \Gamma$ it suffices to show that $\left|F^{(j)}(\rho) G^{(k-j)}(\rho)\right|$ is bounded by the right side of (6.7) for all $j=0,1, \ldots, k-1$. For $j=0$ we have $\left|F(\rho) G^{(k)}(\rho)\right|=\left|\frac{G^{(k)}(\rho)}{G(\rho) \rho^{\varepsilon-k}}\right| \rho^{\varepsilon-k}$ which is bounded by the right side of (6.7). For $1 \leq j \leq k-1$ Twe employ the induction hypothesis to write

$$
\begin{aligned}
&\left|F^{(j)}(\rho) G^{(k-j)}(\rho)\right| \leq \operatorname{const}(d, \delta, \varepsilon, \nu)\left(1+\max _{1 \leq \ell \leq j} \sup _{0<\rho<\delta}\left|\frac{G^{(\ell)}(\rho)}{G(\rho) \rho^{\varepsilon-\ell}}\right|\right)^{j}\left|\frac{\rho^{\varepsilon-j} G^{(k-j)}(\rho)}{G(\rho)}\right| \\
&=\operatorname{const}(d, \delta, \varepsilon, \nu)\left(1+\max _{1 \leq \ell \leq j} \sup _{0<\rho<\delta}\left|\frac{G^{(\ell)}(\rho)}{G(\rho) \rho^{\varepsilon-\ell}}\right|\right)^{j}\left|\frac{G^{(k-j)}(\rho)}{G(\rho) \rho^{\varepsilon-k+j}}\right| \rho^{2 \varepsilon-k}
\end{aligned}
$$

which is bounded by the right side of (6.7).
Lemma 6.9. Let $\varepsilon \in(0 \ldots 1)$ and $\delta \in(0 \ldots \infty)$. Let $F \in C^{d+1}((\delta \ldots \infty))$. If $\sigma \in \mathcal{D}$ satisfies $\sigma=1$ on $\delta B$, then

$$
\sum_{j \in \mathbb{Z}^{d}}\left\|((1-\sigma) F(|\cdot|))^{\vee}\right\|_{L_{\infty}(j+Q)} \leq \operatorname{const}(d, \sigma, \delta, \varepsilon) \max _{0 \leq k \leq d+1} \sup _{\delta<\rho<\infty} \frac{\left|F^{(k)}(\rho)\right|}{\rho^{-d-\varepsilon}}
$$

Proof. First note that

$$
\begin{aligned}
& \sum_{j \in \mathbb{Z}^{d}}\left\|((1-\sigma) F(|\cdot|))^{\vee}\right\|_{L_{\infty}(j+Q)} \leq \operatorname{const}(d)\left\|(1+|\cdot|)^{d+1}((1-\sigma) F(|\cdot|))^{\vee}\right\|_{L_{\infty}} \\
& \leq \operatorname{const}(d)\|(1-\sigma) F(|\cdot|)\|_{W_{1}^{d+1}\left(\mathbb{R}^{d}\right)}, \quad \text { by (extended) Hausdorff-Young Theorem } \Gamma \\
& \leq \operatorname{const}(d, \sigma)\|F(|\cdot|)\|_{W_{1}^{d+1}\left(\mathbb{R}^{d} \backslash \delta B\right)} .
\end{aligned}
$$

Since the functions $p_{\alpha, k}$ are homogeneous of degree $\leq 0$ Гit follows from Lemma 6.1 that

$$
\begin{aligned}
& \|F(|\cdot|)\|_{W_{1}^{d+1}\left(\mathbb{R}^{d} \backslash \delta B\right)} \leq \operatorname{const}(d, \delta) \max _{0 \leq k \leq d+1}\left\|F^{(k)}(|\cdot|)\right\|_{L_{1}\left(\mathbb{R}^{d} \backslash \delta B\right)} \\
& =\operatorname{const}(d, \delta) \max _{0 \leq k \leq d+1} \int_{\delta}^{\infty}\left|F^{(k)}(\rho)\right| \rho^{d-1} d \rho \leq \operatorname{const}(d, \delta, \varepsilon) \max _{0 \leq k \leq d+1} \sup _{\delta<\rho<\infty} \frac{\left|F^{(k)}(\rho)\right|}{\rho^{-d-\varepsilon}} .
\end{aligned}
$$

Proof of Theorem 3.1. In case $\gamma_{0}>0 \Gamma$ and with (ii) in view $\Gamma$ we may assume without loss of generality that $m-d+\varepsilon<\gamma_{0}$. Note that if $\gamma_{0}=0 \Gamma$ then $m=d$. Put $\delta_{1}:=\inf \{t \geq 0:$ $\lambda(t)=0\} \in(0 . . \infty]$.

Claim 6.10. There exists $\mu \in\left(0 . . \gamma_{0}\right] \cup\left\{\gamma_{0}\right\}$ such that

$$
\begin{align*}
& |\phi(x)|=o\left(|x|^{\gamma_{0}-\mu}\right) \quad \text { as }|x| \rightarrow \infty  \tag{1}\\
& (1+|\cdot|)^{\gamma_{0}-\mu}\left(\frac{\nu|\cdot|^{\gamma_{0}}}{\lambda(|\cdot|)}\right)^{\vee} \in L_{1}, \quad \forall \nu \in \mathcal{D}\left(\delta_{1} B\right) . \tag{2}
\end{align*}
$$

proof. Let $\nu \in \mathcal{D}\left(\delta_{1} B\right)$. There exists $\delta \in\left(0 \ldots \delta_{1}\right)$ such that $\nu \in \mathcal{D}(\delta B)$. Define $F(\rho):=$ $\frac{\rho^{\gamma 0}}{\lambda(\rho)} \Gamma \rho \in[0 \ldots \delta]$. Note that $F \in C([0 \ldots \delta])$. That $F \in C^{m}((0 \ldots \delta])$ follows from (iii) and the fact that $\delta<\delta_{1}$. We will show that

$$
\begin{equation*}
(1+|\cdot|)^{m-d+\varepsilon / 2}\left(\frac{\nu|\cdot|^{\gamma_{0}}}{\lambda(|\cdot|)}\right)^{\vee} \in L_{1} . \tag{6.11}
\end{equation*}
$$

In view of Lemma 6.3 (with $n:=m$ ) Гit suffices to show that

$$
\begin{equation*}
\left|F^{(k)}(\rho)\right|=O\left(\rho^{m-d+\varepsilon-k}\right) \quad \text { as } \rho \rightarrow 0, \tag{6.12}
\end{equation*}
$$

for all $1 \leq k \leq m$. Differentiating the identity $\lambda(\rho) F(\rho)=\rho^{\gamma_{0}}$ and solving for $F^{(k)}(\rho)$ yields

$$
\begin{equation*}
F^{(k)}(\rho)=\frac{1}{\lambda(\rho)}\left(\gamma_{0}\left(\gamma_{0}-1\right) \cdots\left(\gamma_{0}-k+1\right) \rho^{\gamma_{0}-k}-\sum_{j=1}^{k}\binom{k}{j} \lambda^{(j)}(\rho) F^{(k-j)}(\rho)\right) \tag{6.13}
\end{equation*}
$$

$1 \leq k \leq m \Gamma 0<\rho<\delta$. Note that for $1 \leq k \leq m \Gamma$

$$
\left|\gamma_{0}\left(\gamma_{0}-1\right) \cdots\left(\gamma_{0}-k+1\right) \rho^{\gamma_{0}-k}\right|=O\left(\rho^{m-d+\varepsilon-k}\right) \quad \text { as } \rho \rightarrow 0
$$

since $m-d+\varepsilon<\gamma_{0}$ is assumed in case $\gamma_{0}>0$. That (6.12) holds in case $k=1$ follows readily from (6.13) $\Gamma$ (iv) $\Gamma$ and the fact that $|F(\rho)|=O\left(\rho^{\gamma_{0}}\right)$ as $\rho \rightarrow 0$. Proceeding by induction $\Gamma$ assume that (6.12) holds for all $k \Gamma 1 \leq k \leq k^{\prime}<m \Gamma$ and consider $k=k^{\prime}+1$. By (iv) and the induction hypothesis $\Gamma$ it follows that

$$
\left|\lambda^{(j)}(\rho) F^{(k-j)}(\rho)\right|=O\left(\rho^{\varepsilon-j}\right) O\left(\rho^{m-d+\varepsilon+j-k}\right)=O\left(\rho^{m-d+\varepsilon-k}\right) \quad \text { as } \rho \rightarrow 0,
$$

for all $1 \leq j \leq k-1$. As for $j=k$ we have by (iv) that

$$
\left|\lambda^{(k)}(\rho) F(\rho)\right|=O\left(\rho^{\varepsilon-k}\right) O\left(\rho^{\gamma_{0}}\right)=O\left(\rho^{m-d+\varepsilon-k}\right) \quad \text { as } \rho \rightarrow 0
$$

Therefore $\Gamma$ in view of (6.13) Гestimate (6.12) holds for $k=k^{\prime}+1$ Гand thus (6.11) is proved.
Case 1. $\gamma_{0}>0$.
Since $\gamma_{0}>\left\lceil\gamma_{0}-\bar{\mu}\right\rceil($ by $($ ii $)) \Gamma$ we must have $0<\bar{\mu} \leq \gamma_{0}$. Hence $\emptyset \neq(0 \ldots \bar{\mu}) \subset\left(0 \ldots \gamma_{0}\right]$. Note that by definition of $\bar{\mu} \Gamma$ condition (1) holds for all $\mu \in(0 . . \bar{\mu})$. On the other hand $\Gamma$

$$
m-d+\varepsilon / 2=\left\lceil\gamma_{0}-\bar{\mu}\right\rceil+\varepsilon / 2 \geq \gamma_{0}-\bar{\mu}+\varepsilon / 2>\gamma_{0}-\mu
$$

for $\mu \in(0 \ldots \bar{\mu})$ sufficiently close to $\bar{\mu}$. Hence $\Gamma$ by (6.11) $\Gamma$ condition (2) holds for some $\mu \in(0 . . \bar{\mu})$.

Case 2. $\gamma_{0}=0$.
With $\mu:=0 \Gamma$ condition (1) follows from (i). In particular $\Gamma \bar{\mu}=0$. Hence $m-d+\varepsilon / 2=\varepsilon / 2$ and thus condition (2) is a consequence of (6.11). Hence the claim.

Let $\delta \in(0 \ldots \pi)$ be such that $\lambda \neq 0$ on all of $[0 \ldots \delta]$. Let $\hat{\eta} \in \mathcal{D}(\delta B)$ satisfy $\hat{\eta}=1$ on $\frac{1}{2} \delta B$. Let $\sigma \in \mathcal{D}(\pi B)$ satisfy $\sigma=1$ on $\delta B$.

Claim 6.14. If $G \in C^{d+1}(\delta \ldots \infty) \Gamma$ then

$$
\sum_{j \in \mathbb{Z}^{d}}\left\|\left((1-\sigma)|\cdot|^{-\gamma_{0}} G(|\cdot|)\right)^{\vee}\right\|_{L_{\infty}(j+Q)} \leq \operatorname{const}\left(d, \sigma, \delta, \varepsilon, \gamma_{0}\right) \max _{0 \leq k \leq d+1} \sup _{\delta<\rho<\infty} \frac{\left|G^{(k)}(\rho)\right|}{\rho^{\gamma_{0}-d-\varepsilon}}
$$

proof. Let $G \in C^{d+1}(\delta \ldots \infty)$ and put $F(\rho):=\rho^{-\gamma_{0}} G(\rho) \Gamma \rho>0$. In view of Lemma 6.9 1 it suffices to show that

$$
\sup _{\delta<\rho<\infty} \frac{\left|F^{(k)}(\rho)\right|}{\rho^{-d-\varepsilon}} \leq \operatorname{const}\left(d, \delta, \varepsilon, \gamma_{0}\right) \max _{0 \leq j \leq d+1} \sup _{\delta<\rho<\infty} \frac{\left|G^{(j)}(\rho)\right|}{\rho^{\gamma_{0}-d-\varepsilon}},
$$

for all $0 \leq k \leq d+1$. That this is true can be seen by noting that for $0 \leq k \leq d+1$ and $\delta<\rho<\infty \Gamma$

$$
F^{(k)}(\rho)=\sum_{j=0}^{k}\binom{k}{j}\left(-\gamma_{0}\right)\left(-\gamma_{0}-1\right) \cdots\left(-\gamma_{0}-(k-j-1)\right) \rho^{-\gamma_{0}-(k-j)} G^{(j)}(\rho) .
$$

Hence the claim.

Claim 6.15. The stationary ladder $\left(S^{h}(\phi ; \Xi)\right)_{h}$ provides $L_{p}$-approximation of order $\gamma_{0}$ for all $1 \leq p \leq \infty$ whenever $\Xi$ is a sufficiently small perturbation of $\mathbb{Z}^{d}$.
proof. In order to apply Theorem $5.8 \Gamma$ put $\phi_{h}:=\phi \Gamma h>0$; then $\lambda_{h}=\lambda(|\cdot|) \Gamma h>0$. It follows from Claim 6.10 (with $\nu:=\widehat{\eta}(\cdot / h)$ ) that there exists $\mu \in\left(0 \ldots \gamma_{0}\right] \cup\left\{\gamma_{0}\right\}$ such that conditions (i) and (ii) of Theorem 5.8 hold. Hence $\Gamma$ in view of Theorem $5.8 \Gamma$ in order to prove the claim it suffices to show that

$$
\begin{align*}
& \sum_{j \in \mathbb{Z}^{d}}\left\|\left((1-\sigma)|\cdot|^{-\gamma_{0}} \lambda(|\cdot|)\right)^{\vee}\right\|_{L_{\infty}(j+Q)}<\infty, \quad \text { and }  \tag{6.16}\\
& \left\|\left(\frac{\widehat{\eta}(\cdot / h)|\cdot|^{\gamma_{0}}}{\lambda(|\cdot|)}\right)^{\vee}\right\|_{L_{1}}=O\left(h^{\gamma_{0}}\right) \quad \text { as } h \rightarrow 0 \tag{6.17}
\end{align*}
$$

That (6.16) holds follows from (iii) $\Gamma$ (v) ) and Claim 6.14 (with $G:=\lambda$ ). So F we now consider (6.17). If $h<1 / 2 \Gamma$ then

$$
\begin{aligned}
& \left\|\left(\frac{\widehat{\eta}(\cdot / h)|\cdot|^{\gamma_{0}}}{\lambda(|\cdot|)}\right)^{\vee}\right\|_{L_{1}}=h^{\gamma_{0}}\left\|\left(\frac{\widehat{\eta}|\cdot|^{\gamma_{0}}}{\lambda(|h \cdot|)}\right)^{\vee}\right\|_{L_{1}}=h^{\gamma_{0}}\left\|\left(\widehat{\eta}|\cdot|^{\gamma_{0}} \frac{\widehat{\eta}(h \cdot)}{\lambda(|h \cdot|)}\right)^{\vee}\right\|_{L_{1}} \\
& \leq h^{\gamma_{0}}\left\|\left(\widehat{\eta}|\cdot|^{\gamma_{0}}\right)^{\vee}\right\|_{L_{1}}\left\|\left(\frac{\widehat{\eta}(h \cdot)}{\lambda(|h \cdot|)}\right)^{\vee}\right\|_{L_{1}}=h^{\gamma_{0}}\left\|\left(\widehat{\eta} \cdot \cdot^{\gamma_{0}}\right)^{\vee}\right\|_{L_{1}}\left\|\left(\frac{\widehat{\eta}}{\lambda(|\cdot|)}\right)^{\vee}\right\|_{L_{1}} .
\end{aligned}
$$

That $\left(\widehat{\eta}|\cdot|^{\gamma_{0}}\right)^{\vee} \in L_{1}$ is an easy consequence of Lemma 6.3 while $\left(\frac{\widehat{\eta}}{\lambda(|\cdot|)}\right)^{\vee} \in L_{1}$ follows from (iii) $\Gamma$ (iv) $\Gamma$ and Lemma 6.6 (with $\nu:=\widehat{\eta}$ and $G:=\lambda$ ). Therefore (6.17) holds and the claim is proved.

Having dispensed with the stationary case $\Gamma$ we turn now to the non-stationary half of the theorem. Assume that there exists $\theta, a, N \in(0 \ldots \infty)$ such that (vi) and (vii) hold. Let $\kappa:(0 . .1] \rightarrow(0 \ldots \infty)$ satisfy

$$
\begin{equation*}
\limsup _{h \rightarrow 0} \kappa(h)^{\theta} \log (1 / h)<\frac{\pi^{\theta}}{\gamma_{1}}, \quad \text { for some } \gamma_{1} \in(0 \ldots \infty) \tag{6.18}
\end{equation*}
$$

and define $\phi_{h}:=\phi(\kappa(h) \cdot) \Gamma h \in(0 . .1]$. Since $\kappa(h) \rightarrow 0$ as $h \rightarrow 0 \Gamma$ we may assume without loss of generality that $\kappa(h) \leq 1 \forall h \in(0 . .1]$. Note that $\widehat{\phi}_{h}=\kappa(h)^{-d} \widehat{\phi}(\cdot / \kappa(h))$ and so on $\mathbb{R}^{d} \backslash 0 \Gamma \widehat{\phi}_{h}$ can be identified with $|\cdot|^{-\gamma_{0}} \kappa(h)^{\gamma_{0}-d} \lambda(|\cdot| / \kappa(h))$. So in the terminology of Theorem $5.8 \Gamma \lambda_{h}=\kappa(h)^{\gamma_{0}-d} \lambda(|\cdot| / \kappa(h)) \Gamma h \in(0 . .1]$. By (vi) $\Gamma \lambda \neq 0$ on all of $[0 . . \infty)$ and hence it follows from Claim 6.10 that there exists $\mu \in\left(0 . . \gamma_{0}\right] \cup\left\{\gamma_{0}\right\}$ such that (i) and (ii) of Theorem 5.8 are satisfied. For $0<r \leq h \leq 1 \Gamma$ put

$$
\Gamma(r, h):=\left\|\left(\frac{\widehat{\eta}(\cdot / h)|\cdot|^{\gamma_{0}}}{\lambda_{r}}\right)^{\vee}\right\|_{L_{1}} \sum_{j \in \mathbb{Z}^{d}}\left\|\left((1-\sigma)|\cdot|^{-\gamma_{0}} \lambda_{r}\right)^{\vee}\right\|_{L_{\infty}(j+Q)} .
$$

ThenTin view of Theorem 5.8 Гin order to complete the proof of our theoremГit suffices to show that

$$
\begin{equation*}
\sup _{0<r \leq h} \Gamma(r, h)=O\left(h^{\gamma_{0}+\gamma_{1}}\right) \quad \text { as } h \rightarrow 0 . \tag{6.19}
\end{equation*}
$$

Note that for all $0<r \leq h \leq 1 \Gamma$

$$
\begin{equation*}
\Gamma(r, h)=h^{\gamma_{0}}\left\|\left(\frac{\widehat{\eta}|\cdot|^{\gamma_{0}}}{\lambda(h|\cdot| / \kappa(r))}\right)^{\vee}\right\|_{L_{1}} \sum_{j \in \mathbb{Z}^{d}}\left\|\left((1-\sigma)|\cdot|^{-\gamma_{0}} \lambda(|\cdot| / \kappa(r))\right)^{\vee}\right\|_{L_{\infty}(j+Q)} . \tag{6.20}
\end{equation*}
$$

By (iii) $\Gamma$ (iv) $\Gamma$ (vi) $\Gamma$ and (vii) $\Gamma$

$$
\begin{aligned}
& C_{1}:=\sup _{0<\rho<\infty} \frac{\exp \left(-a \rho^{\theta}\right)}{|\lambda(\rho)|}<\infty ; \\
& C_{2}:=\max _{0 \leq k \leq d+1} \sup _{\delta<\rho<\infty} \frac{\left|\lambda^{(k)}(\rho)\right|}{\rho^{N} \exp \left(-\rho^{\theta}\right)}<\infty ; \\
& C_{3}:=\max _{1 \leq k \leq d_{0}} \sup _{0<\rho<\infty} \frac{\left|\lambda^{(k)}(\rho)\right|}{\rho^{\varepsilon-k}}<\infty .
\end{aligned}
$$

Claim 6.21. For all $0<r \leq h \leq 1 \Gamma$

$$
\left\|\left(\frac{\hat{\eta}|\cdot|^{\gamma_{0}}}{\lambda(h|\cdot| / \kappa(r))}\right)^{\vee}\right\|_{L_{1}} \leq \operatorname{const}\left(d, \gamma_{0}, \delta, \varepsilon, \eta, C_{1}, C_{3}\right) \kappa(r)^{-d} \exp \left(a(d+1)(h \delta / \kappa(r))^{\theta}\right) .
$$

proof. First of allГ

$$
\begin{equation*}
\left\|\left(\frac{\widehat{\eta}|\cdot|^{\gamma_{0}}}{\lambda(h|\cdot| / \kappa(r))}\right)^{\vee}\right\|_{L_{1}} \leq\left\|\left(\frac{\widehat{\eta}}{\lambda(h|\cdot| / \kappa(r))}\right)^{\vee}\right\|_{L_{1}}\left\|\left(\widehat{\eta}(\cdot / 2)|\cdot|^{\gamma_{0}}\right)^{\vee}\right\|_{L_{1}} . \tag{6.22}
\end{equation*}
$$

Note that $\Gamma$ with $\nu:=\widehat{\eta}$ and $G:=\lambda(h \cdot / \kappa(r)) \Gamma$ the hypothesis of Lemma 6.6 is satisfied. Now $\Gamma$

$$
\begin{equation*}
\max _{1 \leq k \leq d} \sup _{0<\rho<\delta} \frac{\left|G^{(k)}(\rho)\right|}{\rho^{\varepsilon-k}}=(h / \kappa(r))^{\varepsilon} \max _{1 \leq k \leq d} \sup _{0<\rho<\delta} \frac{\left|\lambda^{(k)}(h \rho / \kappa(r))\right|}{(h \rho / \kappa(r))^{\varepsilon-k}} \leq C_{3}(h / \kappa(r))^{\varepsilon} . \tag{6.23}
\end{equation*}
$$

On the other hand $\Gamma$

$$
\begin{equation*}
\sup _{0<\rho<\delta} \frac{1}{|G(\rho)|}=\sup _{0<\rho<\delta} \frac{\exp \left(-a(h \rho / \kappa(r))^{\theta}\right)}{\exp \left(-a(h \rho / \kappa(r))^{\theta}\right) \lambda(h \rho / \kappa(r))} \leq C_{1} \exp \left(a(h \delta / \kappa(r))^{\theta}\right) \tag{6.24}
\end{equation*}
$$

It follows from (6.23) and (6.24) that

$$
\begin{aligned}
& \left(1+\max _{1 \leq k \leq d} \sup _{0<\rho<\delta}\left|\frac{G^{(k)}(\rho)}{G(\rho) \rho^{\varepsilon-k}}\right|\right)^{d} \sup _{0<\rho<\delta} \frac{1}{|G(\rho)|} \\
& \leq \operatorname{const}\left(d, C_{1}, C_{3}\right)\left(1+(h / \kappa(r))^{\varepsilon}\right)^{d} \exp \left(a(d+1)(h \delta / \kappa(r))^{\theta}\right) \\
& \leq \operatorname{const}\left(d, C_{1}, C_{3}\right) \kappa(r)^{-d} \exp \left(a(d+1)(h \delta / \kappa(r))^{\theta}\right),
\end{aligned}
$$

for all $0<r \leq h \leq 1$. In view of (6.22) and Lemma $6.6 \Gamma$ the claim is proved.

Claim 6.25. There exists $h_{1} \in(0 \ldots 1]$ such that

$$
\begin{aligned}
\sum_{j \in \mathbb{Z}^{d}}\left\|\left((1-\sigma)|\cdot|^{-\gamma_{0}} \lambda(|\cdot / \kappa(r)|)\right)^{\vee}\right\|_{L_{\infty}(j+Q)} \\
\quad \leq C_{2} \operatorname{const}\left(d, \sigma, \delta, N, \varepsilon, \gamma_{0}\right) \kappa(r)^{-d-1-N} \exp \left(-\kappa(r)^{-\theta} \delta^{\theta}\right), \quad \forall 0<r \leq h_{1}
\end{aligned}
$$

proof. Put $G:=\lambda(\cdot / \kappa(r)) \in C^{d+1}((\delta \ldots \infty))$. In view of Claim $6.14 \Gamma$ it suffices to show that there exists $h_{1} \in(0 \ldots 1]$ such that for all $0<r \leq h_{1} \Gamma$

$$
\begin{equation*}
\max _{0 \leq k \leq d+1} \sup _{\delta<\rho<\infty} \frac{\left|\frac{d^{k}}{d \rho^{k}}(\lambda(\rho / \kappa(r)))\right|}{\rho^{\gamma_{0}-d-\varepsilon}} \leq C_{2} \delta^{d+\varepsilon+N-\gamma_{0}} \kappa(r)^{-d-1-N} \exp \left(-\kappa(r)^{-\theta} \delta^{\theta}\right) \tag{6.26}
\end{equation*}
$$

Observe that

$$
\begin{aligned}
& \max _{0 \leq k \leq d+1} \sup _{\delta<\rho<\infty} \frac{\left|\frac{d^{k}}{d \rho^{k}}(\lambda(\rho / \kappa(r)))\right|}{\rho^{\gamma_{0}-d-\varepsilon}}=\max _{0 \leq k \leq d+1} \kappa(r)^{-k} \sup _{\delta<\rho<\infty} \frac{\left|\lambda^{(k)}(\rho / \kappa(r))\right|}{\rho^{\gamma_{0}-d-\varepsilon}} \\
& \leq \kappa(r)^{-d-1} \max _{0 \leq k \leq d+1} \sup _{\delta<\rho<\infty} \frac{\left|\lambda^{(k)}(\rho / \kappa(r))\right|}{(\rho / \kappa(r))^{N} \exp \left(-\kappa(r)^{-\theta} \rho^{\theta}\right)} \frac{(\rho / \kappa(r))^{N} \exp \left(-\kappa(r)^{-\theta} \rho^{\theta}\right)}{\rho^{\gamma_{0}-d-\varepsilon}} \\
& \leq C_{2} \kappa(r)^{-d-1-N} \sup _{\delta<\rho<\infty} \rho^{d+\varepsilon+N-\gamma_{0}} \exp \left(-\kappa(r)^{-\theta} \rho^{\theta}\right) .
\end{aligned}
$$

Since $\kappa(r) \rightarrow 0$ as $r \rightarrow 0 \Gamma$ it is a straightforward matter to show $\Gamma$ using elementary differential calculus $\Gamma$ that there exists $h_{1} \in(0 . .1]$ such that

$$
\sup _{\delta<\rho<\infty} \rho^{d+\varepsilon+N-\gamma_{0}} \exp \left(-\kappa(r)^{-\theta} \rho^{\theta}\right)=\delta^{d+\varepsilon+N-\gamma_{0}} \exp \left(-\kappa(r)^{-\theta} \delta^{\theta}\right), \quad \forall 0<r \leq h_{1} .
$$

Hence $\Gamma$ (6.26) holds and the claim is proved.
Therefore $\operatorname{Cby}$ (6.20) ГClaim 6.21Гand Claim 6.25 Гthere exists $h_{1} \in(0 . .1]$ such that

$$
\begin{align*}
& \Gamma(r, h) \leq h^{\gamma_{0}} \operatorname{const}\left(d, \sigma, \delta, N, \gamma_{0}, \varepsilon, \eta, C_{1}, C_{2}, C_{3}\right) \\
& \times \kappa(r)^{-2 d-1-N} \exp \left(\left(a(d+1) h^{\theta}-1\right)(\delta / \kappa(r))^{\theta}\right), \tag{6.27}
\end{align*}
$$

for all $0<r \leq h \leq h_{1}$. Now in view of (6.18) Гand since $\delta$ was chosen arbitrarily in $(0 \ldots \pi) \Gamma$ we may assume without loss of generality that $\delta \in(0 \ldots \pi)$ is sufficiently close to $\pi$ so that

$$
\limsup _{h \rightarrow 0} \kappa(h)^{\theta} \log (1 / h)<\frac{\left(\delta-\varepsilon_{1}\right)^{\theta}}{\gamma_{1}}, \quad \text { for some } \varepsilon_{1}>0
$$

Hence there exists $h_{2} \in\left(0 . . h_{1}\right]$ such that

$$
\kappa(h) \leq \bar{\kappa}(h):=\left(\frac{\left(\delta-\varepsilon_{1}\right)^{\theta}}{\gamma_{1} \log (1 / h)}\right)^{1 / \theta}, \quad \forall 0<h \leq h_{2} .
$$

It can be shown $\Gamma$ by applying elementary differential calculus to (6.27) $\Gamma$ that there exists $h_{0} \in\left(0 . . h_{2}\right]$ such that

$$
\begin{aligned}
& \sup _{0<r \leq h} \Gamma(r, h) \leq h^{\gamma_{0}} \operatorname{const}\left(d, \sigma, \delta, N, \gamma_{0}, \varepsilon, \eta, C_{1}, C_{2}, C_{3}\right) \\
& \times \bar{\kappa}(h)^{-2 d-1-N} \exp \left(\left(a(d+1) h^{\theta}-1\right)(\delta / \bar{\kappa}(h))^{\theta}\right),
\end{aligned}
$$

for all $0<h \leq h_{0}$. Now $\Gamma$ as $h \rightarrow 0 \Gamma$

$$
\begin{aligned}
& \bar{\kappa}(h)^{-2 d-1-N} \exp \left(\left(a(d+1) h^{\theta}-1\right)(\delta / \bar{\kappa}(h))^{\theta}\right)=O\left(\bar{\kappa}(h)^{-2 d-1-N} \exp \left(-(\delta / \bar{\kappa}(h))^{\theta}\right)\right) \\
& =O\left(\bar{\kappa}(h)^{-2 d-1-N} \exp \left(-\left(\frac{\delta}{\delta-\varepsilon_{1}}\right)^{\theta} \gamma_{1} \log (1 / h)\right)\right) \\
& =O\left(\exp \left(-\gamma_{1} \log (1 / h)\right)\right)=O\left(h^{\gamma_{1}}\right)
\end{aligned}
$$

Therefore $\Gamma$

$$
\sup _{0<r \leq h} \Gamma(r, h)=O\left(h^{\gamma_{0}+\gamma_{1}}\right) \quad \text { as } h \rightarrow 0,
$$

which $\Gamma$ in view of (6.19) completes the proof.

## 7. Proof of Theorem 3.7

Our proof of Theorem 3.7 requires the following two lemmata.
Lemma 7.1. Let $0 \leq a<b \leq \infty$ and put $\Omega:=\left\{x \in \mathbb{R}^{d}: a<|x|<b\right\}$. If $F \in C^{d+1}(a \ldots b)$, then

$$
\|F(|\cdot|)\|_{W_{1}^{d+1}(\Omega)} \leq \operatorname{const}(d)\left(\int_{a}^{b} \rho^{d-1}|F(\rho)| d \rho+\max _{1 \leq k \leq \ell \leq d+1} \int_{a}^{b} \rho^{k-\ell+d-1}\left|F^{(k)}(\rho)\right| d \rho\right)
$$

Proof. First note that $\|F(|\cdot|)\|_{L_{1}(\Omega)}=\operatorname{const}(d) \int_{a}^{b} \rho^{d-1}|F(\rho)| d \rho$. For $1 \leq|\alpha| \leq d+1$ we have by Lemma 6.1 that

$$
\begin{aligned}
& \left\|D^{\alpha}(F(|\cdot|))\right\|_{L_{1}(\Omega)} \leq \operatorname{const}(d) \sum_{k=1}^{|\alpha|} \int_{\Omega}|x|^{k-|\alpha|}\left|F^{(k)}(|x|)\right| d x \\
= & \operatorname{const}(d) \sum_{k=1}^{|\alpha|} \int_{a}^{b} \rho^{k-|\alpha|+d-1}\left|F^{(k)}(\rho)\right| d \rho \leq \operatorname{const}(d) \max _{1 \leq k \leq \ell \leq d+1} \int_{a}^{b} \rho^{k-\ell+d-1}\left|F^{(k)}(\rho)\right| d \rho
\end{aligned}
$$

Definition. A function $F:[0 . . \infty) \rightarrow \mathbb{C}$ is said to be $\gamma$ admissable $(\gamma \in \mathbb{R})$ if $F(|\cdot|) \in$ $C^{d+1}\left(\mathbb{R}^{d}\right)$ and
(i) $\sup _{0 \leq \rho<\infty} \frac{(1+\rho)^{\gamma}}{|F(\rho)|}<\infty \quad$ and

$$
\begin{equation*}
\left|F^{(k)}(\rho)\right|=O\left(\rho^{\gamma-k}\right) \text { as } \rho \rightarrow \infty, \quad 0 \leq k \leq d+1 . \tag{ii}
\end{equation*}
$$

The relevance of this definition to Theorem 3.7 is that the function $\lambda$ is $-\gamma$ admissable while the function $1 / \lambda$ is $\gamma$ admissable.

Lemma 7.2. Let $f$ be $\gamma$ admissable and let $\delta>0$. Let $a \in(0 \ldots \infty)$ and define $F(\rho):=$ $f(a \rho), 0 \leq \rho<\infty$. The following hold:

$$
\begin{align*}
& \text { If } \gamma>d \text {, then }\|F(|\cdot|)\|_{W_{1}^{d+1}(\delta B)} \leq \operatorname{const}(d, \delta, \gamma, f)(1+a)^{\gamma} .  \tag{1}\\
& \text { If } \gamma<-d \text { and } a \geq 1 \text {, then }\|F(|\cdot|)\|_{W_{1}^{d+1}\left(\mathbb{R}^{d} \backslash \delta B\right)} \leq \operatorname{const}(d, \delta, \gamma, f) a^{\gamma} . \tag{2}
\end{align*}
$$

Proof. We employ Lemma 7.1. Assume $\gamma>d$. First we have

$$
\int_{0}^{\delta} \rho^{d-1}|F(\rho)| d \rho \leq \operatorname{const}(f) \int_{0}^{\delta} \rho^{d-1}(1+a \rho)^{\gamma} d \rho \leq \operatorname{const}(d, \delta, \gamma, f)(1+a)^{\gamma}
$$

Next assume that $1=k \leq \ell \leq d+1$. Since $f(|\cdot|) \in C^{d+1}\left(\mathbb{R}^{d}\right) \Gamma$ it follows that $F^{\prime}(0)=$ $a f^{\prime}(0)=0 \Gamma$ and consequently we can write $F^{\prime}(\rho)=\int_{0}^{\rho} F^{\prime \prime}(s) d s$. Hence

$$
\begin{aligned}
& \int_{0}^{\delta} \rho^{k-\ell+d-1}\left|F^{\prime}(\rho)\right| d \rho \\
& \leq \operatorname{const}(d, \delta) \int_{0}^{\delta} \rho^{-1} \int_{0}^{\rho}\left|F^{\prime \prime}(s)\right| d s d \rho=\operatorname{const}(d, \delta) \int_{0}^{\delta} \log (\delta / s)\left|F^{\prime \prime}(s)\right| d s \\
& \leq \operatorname{const}(d, \delta, f) a^{2} \begin{cases}\int_{0}^{\delta} \log (\delta / s)(a s)^{\gamma-2} d s & \text { if } \gamma<2 \\
\int_{0}^{\delta} \log (\delta / s)(1+a \delta)^{\gamma-2} d s & \text { else } \quad \leq \operatorname{const}(d, \delta, \gamma, f)(1+a)^{\gamma}\end{cases}
\end{aligned}
$$

Finally $\Gamma$ assume $2 \leq k \leq \ell \leq d+1$. Then

$$
\begin{aligned}
& \int_{0}^{\delta} \rho^{k-\ell+d-1}\left|F^{(k)}(\rho)\right| d \rho \leq \operatorname{const}(d, \delta) a^{k} \int_{0}^{\delta} \rho^{k-2}\left|f^{(k)}(a \rho)\right| d \rho \\
& \leq \operatorname{const}(d, \delta, f) \begin{cases}a^{d+1} \int_{0}^{\delta} \rho^{d-1}(a \rho)^{\gamma-d-1} d \rho & \text { if } d<\gamma<d+1=k \\
a^{k} \int_{0}^{\delta} \rho^{k-2}(1+a \delta)^{\gamma-k} d \rho & \text { else }\end{cases} \\
& \leq \operatorname{const}(d, \delta, \gamma, f)(1+a)^{\gamma}
\end{aligned}
$$

which proves (1). Turning now to (2) $\Gamma$ assume that $\gamma<-d \Gamma a \geq 1 \Gamma$ and $0 \leq k \leq \ell \leq d+1$. Then

$$
\begin{aligned}
\int_{\delta}^{\infty} \rho^{k-\ell+d-1}\left|F^{(k)}(\rho)\right| d \rho & \leq \operatorname{const}(d, \delta, f) a^{k} \int_{\delta}^{\infty} \rho^{d-1}(1+a \rho)^{\gamma-k} d \rho \\
& \leq \operatorname{const}(d, \delta, \gamma, f) a^{\gamma} \int_{\delta}^{\infty} \rho^{d-1+\gamma-k} d \rho \leq \operatorname{const}(d, \delta, \gamma, f) a^{\gamma}
\end{aligned}
$$

which $\Gamma$ in view of Lemma $7.1 \Gamma$ proves (2).
Proof of Theorem 3.7. We employ Theorem 5.8 with $\gamma_{0}=\mu=0$ and $\varepsilon=1$. Note that $\lambda_{r}=\left(\phi\left(r^{\theta} \cdot\right)\right)^{\wedge}=r^{-d \theta} \widehat{\phi}\left(r^{-\theta} \cdot\right)=r^{-d \theta} \lambda\left(r^{-\theta}|\cdot|\right)$. The assumptions on $\phi$ ensure that $\lambda$ is $-\gamma$ admissable. Since $\gamma>d \Gamma$ it follows that $\hat{\phi} \in L_{1}$ and hence condition (i) of Theorem 5.8 holds. Define

$$
\Gamma_{1}(r, h):=\left\|\left(\frac{\widehat{\eta}(\cdot / h)}{\lambda_{r}}\right)^{\vee}\right\|_{L_{1}}=\left\|\left(\frac{\widehat{\eta}}{\lambda_{r}(h \cdot)}\right)^{\vee}\right\|_{L_{1}}=r^{d \theta}\left\|\left(\frac{\widehat{\eta}}{\lambda\left(h r^{-\theta}|\cdot|\right)}\right)^{\vee}\right\|_{L_{1}}
$$

and note that by the (extended) Hausdorff-Young Theorem $\Gamma$

$$
\Gamma_{1}(r, h) \leq r^{d \theta} \operatorname{const}(d)\left\|\frac{\hat{\eta}}{\lambda\left(r^{-\theta} h|\cdot|\right)}\right\|_{W_{1}^{d+1}\left(\mathbb{R}^{d}\right)} \leq r^{d \theta} \operatorname{const}(d, \eta)\left\|\frac{1}{\lambda\left(r^{-\theta} h|\cdot|\right)}\right\|_{W_{1}^{d+1}(\delta B)}
$$

where $\delta$ is the smallest positive real number such that $\operatorname{supp} \hat{\eta} \subset \delta \bar{B}$. Since $\lambda$ is $-\gamma$ admissable $\Gamma$ it follows that $1 / \lambda$ is $\gamma$ admissableГand hence by Lemma 7.2 (1) $\Gamma$

$$
\Gamma_{1}(r, h) \leq r^{d \theta} \operatorname{const}(d, \eta, \gamma, \phi)\left(1+r^{-\theta} h\right)^{\gamma}
$$

Note in particular that (ii) of Theorem 5.8 now follows. Now define

$$
\Gamma_{2}(r):=\sum_{j \in \mathbb{Z}^{d}}\left\|\left((1-\sigma) \lambda_{r}\right)^{\vee}\right\|_{L_{\infty}(j+Q)}=r^{-d \theta} \sum_{j \in \mathbb{Z}^{d}}\left\|\left((1-\sigma) \lambda\left(r^{-\theta}|\cdot|\right)\right)^{\vee}\right\|_{L_{\infty}(j+Q)} .
$$

As was shown in the first display of the proof of Lemma $6.9 \Gamma$

$$
\Gamma_{2}(r) \leq r^{-d \theta} \operatorname{const}(d, \sigma)\left\|\lambda\left(r^{-\theta}|\cdot|\right)\right\|_{W_{1}^{d+1}\left(\mathbb{R}^{d} \backslash \delta^{\prime} B\right)}
$$

where $\delta^{\prime}$ is the largest real for which $\operatorname{supp}(1-\sigma) \subset \mathbb{R}^{d} \backslash \delta^{\prime} B$. Since $\lambda$ is $-\gamma$ admissable and $\gamma>d \Gamma$ we have by Lemma 7.2 (2) that

$$
\Gamma_{2}(r) \leq r^{-d \theta} \operatorname{const}(d, \sigma, \gamma, \phi)\left(r^{-\theta}\right)^{-\gamma}=r^{-d \theta} \operatorname{const}(d, \sigma, \gamma, \phi) r^{\theta \gamma} .
$$

Therefore $\Gamma$

$$
\begin{aligned}
& \sup _{0<r \leq h} \Gamma_{1}(r, h) \Gamma_{2}(r) \leq \operatorname{const}(d, \sigma, \eta, \gamma, \phi) \sup _{0<r \leq h}\left(1+h r^{-\theta}\right)^{\gamma} r^{\theta \gamma} \\
& \quad=\operatorname{const}(d, \sigma, \eta, \gamma, \phi) \sup _{0<r \leq h}\left(r^{\theta}+h\right)^{\gamma}=\operatorname{const}(d, \sigma, \eta, \gamma, \phi)\left(h^{\theta}+h\right)^{\gamma}=O\left(h^{\theta \gamma}\right)
\end{aligned}
$$

which $\Gamma$ in view of Theorem 5.8 「completes the proof.
Acknowledgements. It is with pleasure that I thank Amos Ron for initially suggesting this problem and for the related suggestions and insights which he has offered during our many discussions. Additionally $\Gamma$ I thank the referees for their comments and suggestions $\Gamma$ especially for the comments which motivated the formulation of Theorem 3.7.

[^0]:    ${ }^{1}$ If $\Xi$ is locally finite, then it is not necessary to use the countable axiom of choice here, since for each $j \in \mathbb{Z}^{d}$, we could then define $\xi_{j}$ to be the unique element of the finite set $\Xi \cap\left(j+\delta_{0} \bar{Q}\right)$ which is least in a lexicographical ordering of $\mathbb{R}^{d}$.
